Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (*a*) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (*b*) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (*a*) or (*b*) will not be re-examined therein.

Part III. includes: Midwifery, Gynæcology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of registration as a medical student.

Section 2.—This section consists of two parts:

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

Fees.—Primary examination, £5 5s.; final examination, £15 15s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The Gillson scholarship in Pathology of the annual value of £90, tenable for one year, is open to Licentiates of the Society and to candidates for the diploma who obtain it within six months of election to the scholarship. An examination in the art of prescribing is held annually, in January, at which the following prizes are awarded:—A gold medal of the value of £6; a silver medal, and a prize of books to the two best candidates.

LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lecturers, residential terms, and detailed information will be found, as a rule, in our advertisement columns.

St. Bartholomew's Hospital.—This hospital has 750 beds, and for many years past the school attached has had a larger number of students than any other medical school in London. Laboratories have been specially equipped for the study of pathology, bacteriology, chemistry, biology, physics, and chemical pathology, and two additional operation theatres have just been built. A new block of buildings has just been completed at a cost of £120,000, and contains new casualty and out-patients' departments, eight special departments, quarters for the junior staff, a dining hall and a common-room for students, &c. Collegiate residence is permissible, subject to the ordinary rules.

Appointments.—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Chief assistants and clinical assistants are appointed in each of the special departments. In-patient dressers, in-patient clinical clerks, clerks, and dressers to the assistant physicians, and assistant surgeons, and to the physicians and surgeons in charge of special departments, are appointed every three months without fee.

Scholarships, &c.—There are four open scholarships in science, £75, £75, £150, £50, tenable for one year, and an Entrance Scholarship in Arts, value £100, and the Jeaffreson exhibition, value £20; at the end of first year four junior scholarships of £30, £20, £25, £15, respectively; Treasurer's prize for practical anatomy; Foster prize in practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Brackenbury scholarships, of £39, in medicine and surgery; Bentley prize, for reports of cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skynner prize of £15; Sir G. Burrows' prize of £10; Matthews Duncan prize, medal and about £20; Willett medal and Walsham prize; Holden Research Scholarship in Surgery, value £105.

Composition Fees.—(1) For students commencing their medical studies, one sum on entrance, 165 guineas; or by four instalments of 45 guineas. (2) For students who have passed an examination in preliminary science, in one sum on entrance, 145 guineas; or by instalments. (3) For students who have finished two years of medical study but have not passed an examination completing their anatomical and physiological studies; if paid in one sum on entrance, 110 guineas; or by annual instalments. (4) For students who have completed three years of medical study but have not passed an examination in anatomy and physiology; 90 guineas; or by annual instalments. (5) University students who have passed an examination completing their anatomical and physiological studies, in one sum, 80 guineas; or by instalments.

Fees for preliminary scientific students:—20 guineas; for laboratory instruction for D.P.H., 15 guineas. Fuller details will be supplied on application to the Dean.

Charing Cross Hospital.—The school attached to this hospital is situated in Central London, and contains new physiological, pathological, and bacteriological laboratories, materia medica and anatomical museums, an anatomical theatre, enlarged dissecting-rooms, and chemical theatre. Clinical instruction is given in medicine, surgery, and obstetrics, and in the special department, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopædic, Röntgen and electrical departments.

The school is complete in all departments, with special teachers for all preliminary and intermediate subjects.

Entrance Scholarships are awarded annually to the value of £575.

Appointments.—The curator and pathologist are appointed annually at £100 a year each. Medical and surgical and obstetric registrars (annual) £40 a year each with luncheon in the hospital. Six house physicians, six house surgeons, and two resident obstetric officers are appointed each year, after competitive examinations. They are provided with board and residence in the hospital.

Fees.—The fees for the five years' curriculum may be paid either by composition fee, payable in one sum, on joining, 115 guineas, or by sessional payment system—Entrance fee, 10 guineas. In addition a sum of 15 guineas must be paid at the beginning of every winter session, and one of 10 guineas at the beginning of every summer session so long as the student remains in the school. Payment may also be made for individual classes and hospital practice when taken separately. Students of any university in the United Kingdom who have passed the examinations in anatomy, physiology, chemistry, and other preliminary subjects, may here complete their studies (except vaccination and attendance at a fever hospital) on payment of a fee of 74 guineas in one sum, or of 80 guineas in two sums, viz., one of 43 guineas on entry, and one of 37 guineas a year later.

The fees for dental students for the two years' curriculum may be paid:—(*a*) in one sum of 55 guineas on entry; (*b*) in two instalments—one of 31 guineas on entry; and the second of 30 guineas at the end of the first twelve months.

Prospectus and further information can be obtained on application to the Dean.

St. George's Hospital.—This hospital is situated in the West End, facing Hyde Park. It contains 351 beds, and special wards for ophthalmic cases and diseases of women.

Appointments.—Eight house physicians and eight house surgeons, entitled to reside and board in the hospital free of expense; twelve general assistants, six assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £50 and board and residence in the hospital; curator of the museum with a salary of £200; assistant curator with a salary of £100; a medical registrar, with a salary of £200 per annum; a surgical registrar with a salary of £200 per annum; an administrator of anæsthetics with a salary of £50 and two with salaries of £30 per annum. All offices are open to candidates without additional fee.

By arrangement with the University of London, all students for the first, second, and third years of the curriculum carry out the necessary courses of instruction at either King's College or University College. The entire teaching of the school is devoted to clinical subjects.

There are two scholarships open to University students, particulars of which will be furnished by the Dean.

Fees.—For first year, £21 or £26 5s., according to the course. For second and third years, £57 15s. in one sum or £63 in two instalments. Students entering their names on the books before commencing this preliminary or intermediate subjects pay no entrance fee. Entrance fee, 10 guineas; annual composition fee, 30 guineas.

Guy's Hospital.—This hospital is situated on the Surrey side of London Bridge, and contains 602 beds in constant occupation. There are special wards for ophthalmic and obstetric cases, eight beds in the latter being appropriated for difficult cases of labour. Some beds have also been set apart for diseases of the ear and throat, and an "isolation" ward for cases of infectious diseases arising in the hospital has been constructed. An obstetric registrar and tutor and two clinical assistants and registrars in the ophthalmic department are appointed to augment the teaching in the special departments, in addition to those attached to the general surgical and medical wards. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England; the facilities thus afforded of completing the whole course of dental study including the pupilage in mechanical dentistry within the walls of one hospital will be appreciated by those intending to practise dentistry. A new museum for pathological specimens and additional lecture and class rooms were opened in 1906.

Appointments.—Eight house surgeons, eight house physicians, eight assistant house physicians, sixteen out-patient officers, sixteen assistant house surgeons, eight obstetric residents, two ophthalmic house surgeons, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships.—Open scholarships of £100 and £50 in classics, mathematics, and modern languages. Open scholarships of £150 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. The following are the scholarships, prizes, and medals open to students of the hospital:—Junior prizes for general proficiency, £20, £15, £10; Hilton prize for dissection, £5; Michael Harris prize for anatomy, £10; Sands Cox scholarship for physiology, £15; Wooldridge prize for physiology, £10; Beaney prize in pathology, £34; Golding-Bird prize in bacteriology, gold medal and £20; Treasurer's gold medal in clinical medicine; Treasurer's gold medal in clinical surgery; Beaney studentship in materia medica (tenable for 3 years), annually £31 10s.; Gull studentship in pathology (tenable for 3 or 5 years), annually £150. The Arthur Durham travelling scholarship of the value of £100, triennially.

Fees.—A new system for payment of composition fees has been instituted at this school. Particulars may be obtained on application to the Dean, Guy's Hospital, London Bridge, S.E.

King's College Hospital.—This hospital is centrally situated, being contiguous to the Royal College of Surgeons, Lincoln's Inn Fields. The College adjoins Somerset House and is close to the hospital, in which there are 220 beds available for clinical teaching; ophthalmic, ear, throat, skin, and dental departments are attached to the hospital. Some wards are specially devoted to children's diseases. The wards have been refloored and the electric light is installed throughout.

Scholarships.—Two scholarships of the value of £100 each; a scholarship, value £50, is open to students of a British University who come up to London to complete their curriculum; and one of £40 for fifth year students. In addition, students may compete for the Carter, Todd, Tanner prizes, and all class and clinical prizes.

Appointments.—Medical and surgical Sambrooke registrarships, tenable for two years, each £50 per annum. Resident hospital appointments, *viz.*, senior and junior house physicians, assistant house physician, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; and senior and junior clinical assistants in special departments.

Special courses of lectures and practical instruction in the chemical, physical, physiological, and other laboratories have been arranged for students preparing for preliminary scientific, intermediate, M.B., and other examinations of the University of London.

F.R.C.S. Examinations.—Special classes are arranged for the final F.R.C.S. examinations. Further particulars can be obtained from the Dean.

The London Hospital.—This hospital is the largest in Great Britain, containing, as it does, 914 beds. It has, moreover wards and a teaching staff for almost every special department in the domain of medicine; the scholarships and prizes are many and valuable.

The additional buildings for the department of public health, for the biological, chemical, and physical laboratories, materia medica museum, vaccinotherapy, &c., and the new bacteriological department with general laboratory, research laboratories and class rooms for D.P.H. work are now open.

Appointments.—The "House" appointments, which are numerous, are made without fee of any kind, and all resident officers are provided with free board and rooms, and in some instances with salary also.

Fees.—Perpetual fee for lectures, demonstrations and hospital practice, payable in three instalments of 45, 45, and 40 guineas at the commencement of the first, second, and third years respectively, 130 guineas; or, if in one payment, 120 guineas. Fee for students entering in their third year (their first and second years having been spent at a recognised medical school, elsewhere) 60 guineas. This fee is payable by students entering who have passed the first M.B. Oxford; the second M.B. Cambridge; or the Intermediate M.B. London. Dental students (general hospital practice and lectures), 40 guineas. General fee for dental practice, 10 guineas.

Note.—A reduction of 15 guineas will be allowed to the sons of medical men from the perpetual fee if paid in full, or 5 guineas from each instalment.

Special entries can be made either for single courses of lectures or for hospital practice. Residential accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train. Fuller particulars can be obtained of the Warden, Mr. Munro Scott.

St. Mary's Hospital.—This hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 281 beds. The new wing, the ground-floor of which, comprising the new out-patient department, was opened in 1898, is now completed, and will be opened as soon as funds will permit; this will raise the number of beds to 350, and provide additional operating theatres. The Inoculation Department, instituted in 1906, has greatly expanded, and has been transferred to a series of rooms in the New Wing of the hospital.

The Department is under the personal supervision of Sir Almroth Wright, F.R.S.

The Athletic Ground (eight acres) is situated at North Kensington, and is easy of access from the Hospital.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anæsthetists are appointed in each year, and receive board and residence in the Hospital.

Scholarships, &c.—One scholarship in natural science, of the value of £145, open to any gentleman who has not completed a winter session of study at a medical school. One scholarship in natural science, of the value of £78 15s., and two of £52 10s., under the same conditions. Two scholarships, each of 60 guineas, open to students from any British University. The scholarships will be awarded by examination on September 23rd, 24th, and 27th.

Fees.—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £145.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 60 guineas in one sum, or 65 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

Preliminary Scientific Course.—A complete course of instruction in chemistry, physics, and biology, recognised by the University of London as an approved course for internal students, is held throughout the year. Students may join in October, January, or April.

MIDDLESEX HOSPITAL.—This hospital, which is conveniently situated in the centre both of business and residential London, contains 340 beds. There are special departments for cancer, and for ophthalmic, throat, aural, skin, dental, children's diseases, and electrical treatment (X-ray and Finsen light). Wards are also devoted to cases of uterine disease. Residence for students is obtainable in the residential college, which has its frontage on the hospital garden.

A Bacteriological and Public Health Laboratory has been added for the purpose of providing instruction for women medical practitioners preparing for the examinations for the Diploma in Public Health and for the M.D. in State Medicine of the University of London, and of affording facilities to them and other women students desirous of carrying out Research Work in Public Health, Bacteriology, and General Pathology.

Appointments.—Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing.

Scholarships, &c.—Two entrance scholarships of the value of £100 and £75 in Arts and Science respectively. One entrance scholarship of the value of £50, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology.) "Emden" Cancer Research Scholarship, £100. "Richard Hollins," Research Scholarship, £105. Two Broderip scholarships of £60 and £40 respectively, for medicine and surgery; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21 for students in their final year. Hetley clinical prize, value £25, awarded annually for proficiency in practical clinical medicine, surgery, and obstetrics; the Lyell Gold Medal and scholarship, value £55, in surgery and surgical anatomy; the Leopold Hudson prize, value 11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynæcology; an exhibition of 10 guineas for anatomy and physiology to second years' students as well as class prizes in all subjects.

Fees.—General fee for the entire course of hospital practice and lectures, 135 guineas, if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas, payable at the commencement of the first, second, and third years respectively. For those who have completed their anatomical and physiological studies the fee is 70 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students is 145 guineas. For those who have passed the preliminary science examination 120 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

ST. THOMAS'S HOSPITAL.—This hospital, with medical school attached, is situated on the southern Embankment of the Thames, facing the Houses of Parliament and contains 602 beds, in constant use. The school buildings, which are separated from the hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading-room, and a very complete museum and gymnasium.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging. Four hospital registrars, two at an annual salary of £100 each, and two at £50 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. Four resident house physicians, two resident obstetric house physicians, and two ophthalmic house surgeons are appointed each six months, also out-patient officers, and clinical assistants in the special departments.

Scholarships, Prizes, &c.—Three entrance scholarships are offered for competition in September, *viz.*, one of £150 and one of £60 in chemistry, physics, and biology at the commencement of the second year; one of £50 open to University students who have passed in anatomy and physiology, for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London Medical school. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology, and the Louis Jenner research scholarship, £60, for pathological research.

Special courses of instruction for the Preliminary Scientific and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S. are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners and others who receive students into their houses. The prospectus of the school may be obtained on application to Mr. G. Q. Roberts, Secretary of the Medical School.

Fees.—A new system for payment of composition fees is in operation. Full details may be obtained of the Secretary.

UNIVERSITY COLLEGE HOSPITAL AND MEDICAL SCHOOL.—The hospital with college opposite are situated in Gower Street, not far from Euston railway terminus, and the Medical school in University Street, connected with the hospital by a subway. The number of beds available for teaching purposes is 277.

The new buildings for University College Hospital completed by the generosity of the late Sir Blundell Maple, Bart., were opened by H.R.H. the Duke of Connaught, on Tuesday, November 6th, 1906.

The new buildings for the Medical School, erected through the generosity of Sir Donald Currie, contain accommodation for undergraduate and post-graduate students in all departments of medical study subsequent to the intermediate course.

Appointments.—Eight house physicians, eight house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants are selected annually by examination from among the senior students, without fee. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, and receive their board and lodging free.

The offices of out-patient physicians' and surgeons' assistants, clinical clerks, surgeons' dressers, and ophthalmic surgeons' assistants are filled by pupils who are also students of the college, without additional fee.

Scholarships, &c.—Entrance scholarship of the value of 135 guineas, and two exhibitions of 55 guineas each, and the Epsom free medical scholarship for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 80 guineas each, the subjects being anatomy and physiology; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison's scholarship, value £55, tenable for two years; Sharpey physiological scholarship, value about £105 a year; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery; Dr. Fellowes' clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology, and other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study. The Tuffnell scholarship of £80 for chemistry two years; and the clothworkers' exhibition in chemistry and physics of £30 each, can also be held in the medical faculty.

Composition Fees.—The following have been grouped to meet the requirements of the various examining boards: A.—For the Courses required by the University of London. 1. For the Preliminary Scientific Course: 25 guineas, entitling to one attendance. 2. For the Intermediate Course: 55 guineas, if paid in one sum; 60 guineas if paid in two instalments. 3. For the Final M.B., B.S. Course: 80 guineas, if paid in one sum; 82 guineas, if paid in two instalments. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham.

B.—For the Medical education required by the Examining Board in England and the Society of Apothecaries: 4. For the Course required for the First Examination: 20 guineas entitling to one attendance. 5. For the Second: 55 guineas, if paid in one sum; 60 guineas, if paid in two instalments. 6. For the Course required for the Third Examination: 80 guineas, if paid in one sum; 82 guineas, if paid in two instalments.

The composition fee in each case entitles to attendance on Lectures and Hospital Practice during three years.

C.—For Dental Students. Composition fee for the Courses required for the L.D.S., 65 guineas; or exclusive of chemistry, practical chemistry, physics, and materia medica, 50 guineas.

Students may repeat attendance at the Courses in chemistry and physics for £3 3s. (inclusive) and in elementary biology for £2 2s.

It should be noted that under the arrangement with the University of London, that body controls the medical science section of the medical school now, while the advanced medical subjects, that is the subjects after the intermediate course, are controlled by the University College Hospital Medical School.

Westminster Hospital.—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the Metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The class rooms, dissecting rooms, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

Appointments.—Medical and surgical registrars, each £50 per annum; two house physicians, three house surgeons, one assistant house physician, one assistant house surgeon, and a resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Qualified students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—(*a*) Winter Session—The Guthrie scholarship £60, entrance scholarship £40, entrance scholarship £30, dental scholarship £20; subjects, Latin, mathematics, English, and either Greek, French, or German. University scholarships, £60 and £40; subjects, anatomy and physiology. Natural science scholarship, £60, subjects, same as for Prel. Sci. of University of London. Natural science scholarship, £40, subjects, chemistry and physics. Free presentation, open to pupils of Epsom Medical College. (*b*) Summer Session.—Natural science scholarship, £60, same as winter. Natural science scholarship, £40, same as above. Arts scholarship, £60, arts scholarship, £40, University scholarships, £60, subjects same as in winter session. (*c*) Prizes, to be competed for by unqualified men. Chadwick, 20 guineas for students of any year not exceeding fifth. Bird medal and prize, £14 for students who have completed fourth winter session. Sturges prize in clinical medicine, £10, clinical surgery prize, £5. And class prizes in the various subjects.

Fees.—(*a*) For course required by Conjoint Board. In one payment of 120 guineas, or two payments of 65 guineas each, payable on entrance and at the commencement of second year respectively, or by six payments, distributed over six sessions, of 24 guineas each. (*b*) For the entire course of the University of London the composition fee is 130 guineas. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments, of £27 10s each.

London School of Medicine for Women (Royal Free Hospital).—The school is situated in Hunter Street, Brunswick Square, and the Royal Free Hospital is in Gray's Inn Road, close by. The school was re-built in 1898, and the laboratories are fully equipped for all the work required for the preliminary Scientific and Intermediate M.B. examinations of the University of London. A course of study is specially arranged for the work required by the Conjoint Colleges of Scotland and the Society of Apothecaries. Students are also prepared for the examinations of the various Universities. The Royal Free Hospital contains 165 beds available for clinical study; and there is a large out-patient and casualty department. In addition to the ordinary systematic lectures at the school, clinical lectures are given at the hospital in medicine, surgery, obstetrics, ophthalmology, and dermatology. Students hold clerkships and dresserships in each department.

Appointments.—A house physician, house surgeon, and a senior and junior resident obstetric assistant are appointed yearly. There are also non-resident appointments, including the anæsthetist and assistant anæsthetists, assistant and clinical pathologists, medical and surgical registrars, curator of museum and clinical assistants.

Fees.—The fee for the Intermediate and Final M.B. University of London course is £135 in one sum, or £145 in the following instalments:—first year, £45; second year, £40; third year, £40; fourth year, £20. The fee for the Preliminary Science classes is £25. The fee for the course for the Conjoint Colleges or Society of Apothecaries, including Elementary Science, is £140 in one sum, or in the following instalments:—first year, £50; second year, £40; third year, £40; fourth year, £20. Particulars as to Scholarships, &c., can be obtained from the Secretary, Miss Douie, M.B., 8 Hunter Street, W.C.

EXTRA-ACADEMICAL INSTITUTIONS IN LONDON.

Royal Institute of Public Health.—The Royal Institute of Public Health, was founded in the year 1886, with the object of obtaining the registration of public health diplomas and the further statutory requirement that all Medical Officers of Health should possess such a qualification, by which means it has succeeded in placing at the head of every public health administration in the Kingdom, a properly trained and specially qualified medical officer. The Council, with the object of providing a Central Institution in London, not only for instruction for the diploma and for scientific work in connection with public health, but also one to which those engaged or interested in preventive or tropical medicine may resort have acquired large and important premises in Russell Square, for the purposes of the Institute, providing a common room for the use of Fellows and Members, a lecture room, a reference library, laboratories for bacteriological and chemical and physical research, and laboratories in which the course of instruction for the diploma in public health can be taken, fitted up with all modern improvements.

The Institute is recognised as a public educational institution by the University of London, and its courses of instruction by the Universities and the Royal Colleges of Physicians and Surgeons. In pursuance of the above objects, the Institute publishes monthly *The Journal of the Royal Institute of Public Health.* Facilities are also afforded for municipal authorities, private medical practitioners, and others to obtain bacteriological and chemical reports.

The Institute is under the patronage of His Majesty the King, and the teaching staff consists of the Principal, Professor William R. Smith, M.D., D.Sc., F.R.S.E., Barrister-at-law; Demonstrator of Bacteriology, Carl Prausnitz, M.D., Breslau; Demonstrator of Chemistry, Mr. C. E. Harris, Ph.D.; Lecturer on Parisitology, Dr. Louis Sambon.

The next annual Congress (1908) will take place at Buxton.

THE ROYAL DENTAL HOSPITAL.—The teaching and hospital practice at this institution (situated in Leicester Square) are recognised by the various examining bodies. The new hospital and school which was opened six years ago, is complete in every detail with modern appliances. The clinic of the hospital is unrivalled, no less than 99,760 cases being treated in 1906. The following scholarships and prizes are open to all full term students:—Entrance scholarship, of the value ot £20, awarded in October. Subjects: Chemistry and dental mechanics. Saunder scholarship, of the value of £20, awarded to the student obtaining the highest aggregate number of marks in the various class examinations. Storer-Bennet research scholarship of the value of £50, awarded once in three years; the Alfred Woodhouse scholarship of £35, and the Robert Woodhouse prize of the value of £10, for practical dental surgery. Class prizes are awarded by the various lecturers. Provision is made for teaching mechanical dentistry, as required by the Royal College of Surgeons, the pupils being under the guidance of the staff of dental surgeons assisted by specially appointed demonstrators. The school contains an excellent library and a well-arranged museum.

Fees.—For the two years' hospital practice and lectures as required by the Royal College of Surgeons of England, the fee is £53 3s. in one instalment, or £55 13s. in two yearly instalments. The fee for the complete curriculum, namely, two years' instruction in mechanical dentistry and two years' hospital practice and lectures, is £150 if paid in one instalment, or 150 guineas if paid in three instalments of 50 guineas. For one year's instruction in mechanical dentistry the fee is 50 guineas. For one year's hospital practice, £21. The necessary course of two years at a general hospital can be taken simultaneously with that at the Royal Dental Hospital. Further particulars can be obtained on application to the Dean.

NATIONAL DENTAL HOSPITAL.—This institution is centrally situated (Great Portland Street, W.), and excellent teaching facilities and hospital practice are here obtainable, special demonstrations being given by members of the staff. There are also a mechanical laboratory, bacteriological laboratory, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools, on October 1st. The medical tutors hold special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £20, and the Rymer prize of £5 5s., the examinations for which are held in May and October. The fee for two years' hospital practice required by the curriculum, including lectures, is £40. (See advt.)

The two years' training in dental mechanics, required by the R.C.S. Curriculum, can be taken in the Mechanical Laboratory, and there is a "Composition Fee" including all the dental subjects of the curriculum of £120.

WOMEN AND CHILDREN.

THE HOSPITAL FOR WOMEN, Soho Square.—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynæcology open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, and certificate, £8 8s.

THE SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone Road, N.W., offers excellent opportunities to qualified medical men for clinical study and training in the details of operative gynæcology. Fee: three months, £3 3s. The success of the staff in this department has gained for them a European reputation. There are 51 beds.

Medical students are admitted to the practice of the following Metropolitan hospitals, to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.

WEST LONDON HOSPITAL, Hammersmith.—This contains 175 beds, and has an extensive out-patient department. Dresserships and clinical clerkships may be obtained. Two house surgeons and two house physicians are selected every six months. There are special departments for diseases of the throat, nose and ear, skin, women and children, and deformities. Electrical and X-ray departments have also been added. The practice of this hospital is reserved exclusively for medical men, junior students not being admitted.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.—This institution has been greatly enlarged, contains 167 beds, cases in various special departments are treated, and the hospital is now recognised for study during the fifth year by the Conjoint Board. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

BETHLEM ROYAL HOSPITAL.—In this Royal institution only cases of lunacy are received, and students intending to pursue this special branch have the best possible opportunities afforded here. The hospital contains 300 beds, and two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Post-graduate lectures are also given.

NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM, Queen Square, W.C.; contains 200 beds. This institution is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

LONDON TEMPERANCE HOSPITAL.—The hospital contains 110 beds, and is conducted as its name implies on non-alcoholic principles by an excellent staff. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

METROPOLITAN HOSPITAL, Kingsland.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

PRINCE OF WALES HOSPITAL TOTTENHAM.—This hospital contains medical and surgical wards and a ward for children, having in all 73 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat and nose, and skin diseases. It has now been authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees.

HOSPITALS FOR CONSUMPTION.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 321 beds in the two buildings. There are four house physicians who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at four o'clock, save during the vacations. Terms, £2 2s. for three months; £5 5s. perpetual. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

Mount Vernon Hospital, Hampstead and Northwood.—This institution, formerly called the North London Consumption Hospital, now carries on its work at Hampstead with 145 beds, and at Northwood with 100 additional beds, where treatment is carried out on the most modern lines, including the "open air" and other systems. Students are admitted to the practice of the hospital under certain conditions, and post-graduate courses are regularly delivered during the year.

City of London Hospital for Diseases of the Chest, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 164 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

Royal Hospital for Diseases of the Chest, City Road.—(80 beds.)—This hospital has been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

Throat and Ear Hospitals.

Hospital for Diseases of the Throat, Golden Square, W.—This hospital has been recently rebuilt and contains 40 beds. Clinical instruction is given daily in the Out-patient Department on diseases of the nose, throat, and ear, and systematic courses of lectures are given during the winter session. There are nine clinics weekly, and an annual out-patient attendance of nearly 50,000. Major and minor operations daily (Mondays excepted) in different theatres. Four senior and thirty-six junior clinical assistants are appointed from among the students to assist the surgeons. Students are admitted to the practice of the hospital at the following fees:—Three months, £5 5s.; six months, £7 7s.; longer periods, £10 10s. Further details can be had by applying to the Dean.

Central London Throat and Ear Hospital.—This hospital contains accommodation for 22 in-patients, and new operating theatre. It has a very extensive out-patient department (over 50,000 attendances yearly), which is open daily to all medical practitioners and students, for the purpose of clinical demonstration and instruction. Courses of practical teaching are held twice weekly by members of the staff, which are open to qualified practitioners and advanced students. Each course is of about six weeks' duration, and includes hospital attendance for that period. The fee is 2 guineas.

Operations are performed daily (Saturday excepted) at 2 p.m.

Special attention is devoted to scientific work in the newly equipped laboratory. Full particulars will be supplied on application to the Dean.

Metropolitan Ear, Nose, and Throat Hospital.—The hospital was founded in 1838, and is situated in Grafton Street, Tottenham Court Road. The out-patient department is open daily at 2.30 p.m. to practitioners and students for acquiring clinical instruction and technical knowledge. Operations are performed on in-patients on Tuesdays, Wednesdays, and Thursdays at 9 a.m. Fee for one month's attendance at the hospital one guinea, and for three months two guineas. During the forthcoming session demonstrations will be given by members of the staff on the pathology and treatment of diseases of the ear and respiratory passages. Short practical classes will also be held in clinical pathology and surgical anatomy. Weekly clinical lectures are given by the staff on the special disease treated at the hospital.

Royal Waterloo Hospital for Children and Women.—This important institution, situated in South London has been in a transition state for some time past, having been partly rebuilt and appointed on ambitious lines, and when completed, as it is expected it will be soon, will contain 200 beds.

Hospital for Sick Children, in Great Ormond Street, Bloomsbury, and Cromwell House, Highgate.—Fee for three months' attendance, £3 3s.; perpetual, £5 5s. There are now 222 beds, besides 38 additional at the convalescent branch.

The practice of the Hospital is open to qualified medical men, and to students who have completed four years of medical study, the Hospital having been recognised by the Conjoint Board of England as a place where six months of the fifth year may be spent in clinical work. There are special ophthalmic, aural, dental, and electrical departments. There is also a Museum and Library in connection with the School. Lectures are given every Thursday afternoon during session by members of the staff, and certificates are granted.

For tickets and further information, apply to the Secretary, by letter, or by calling at the Hospital.

Eye Hospitals.

Royal London Ophthalmic Hospital, formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the Secretary.

Royal Westminster Ophthalmic Hospital, adjoins Charing Cross Hospital in King William Street. It has about 40 beds and a very large out-patient *clinique*. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

Royal Eye Hospital, St. George's Circus, Southwark.—There are 40 beds and two cots. Fees, £2 2s. for three months, £3 3s. for six months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

Central London Ophthalmic Hospital.—This hospital is situate in the Gray's Inn Road, has 26 beds and a large out-patient clinique. The post of clinical assistant is open to both men and women, who must be duly qualified and registered practitioners. During the winter session commencing in October lectures and demonstrations will be given in all the branches of ophthalmology. For syllabus and further particulars apply to the Dean.

Skin Hospitals.

St. John's Hospital for Diseases of the Skin.—Out-patient department, Leicester Square; In-patient department, Uxbridge Road, W. This hospital has a well-equipped in-patient department, with 50 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. During the past year the free course of Chesterfield Lectures given by Dr. Morgan Dockrell has proved a great success, being well attended by the profession. The next course (free) will commence on Thursday, October 3rd, at 6 p.m., in the Lecture Room of the Hospital, Leicester Square. The subject of the opening lecture will be "The Present Position of Dermatology." The Out-patient Department has recently been rebuilt at a cost of £10,000, and contains a spacious laboratory and special electrical department which can be seen in operation every afternoon except Saturday. Clinical demonstrations are given every Monday (Dr. Morgan Dockrell) at 2 p.m.; Wednesday (Dr. Savill) at 3 p.m.; and Tuesday (Dr. Eddowes), at 2 p.m., on Selected Cases. (See Advt.)

One of the oldest institutions of the kind is the Western Skin Hospital (Great Portland Street), which was started as long ago as 1851. The practice of the hospital is open to students and practitioners. Students of this specialty have also the London Skin Hospital, in Fitzroy Square, with seven beds and an out-patient department of over 1,400. There is also the Stamford Street Skin Hospital, in the southern part of the Metropolis, with 10 beds and an out-patient department of 5,600, so that the students' needs in this direction are well catered for.

METROPOLITAN POST-GRADUATE INSTITUTIONS.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—This institution affords to medical men special facilities for acquiring technical skill, and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated in Chenies Street, Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscope room, a library and museum, and reading and smoking rooms. *Cliniques*, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Lectures on Medicine, Surgery, and other allied subjects are delivered on Mondays, Tuesdays, Wednesdays, and Thursdays at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and a vacation session of three weeks' duration, are held during the year, the subjects taught comprising ophthalmology, otology, clinical microscopy, laryngology, urinary analysis, gynæcology, applied anatomy, nervous diseases, and practical X-ray work. There are, in addition, extra-mural classes in operative surgery and practical anatomy with dissecting. Special tutorial classes in medicine, surgery, midwifery, and pathology for gentlemen reading for the higher qualifications have recently been instituted, and are conducted regularly throughout the year.

A complimentary ticket for three days, admitting to *cliniques* and lectures, is issued to any medical practitioner on personal application at the college. The annual subscription for medical practitioners of either sex, holding qualifications granted in any of H.M.'s dominions—wherever resident—is One Guinea. Full information may be obtained from the medical superintendent, Mr. Hayward Pinch, F.R.C.S., 22, Chenies Street, Bedford Square.

WEST LONDON POST-GRADUATE COLLEGE.—The West London Hospital, Hammersmith Road, W., contains 160 beds; the post-graduate course was started in 1895, and this is the original post-graduate college in London attached to a general hospital. Instruction is given in the out-patient department daily at 2.15 p.m. by the assistant physicians and assistant surgeons. The physicians and surgeons attend daily at 2.30 p.m., when post-graduates can accompany them in their visits to the wards. Operations are performed daily at 2.30 p.m. There are lectures every evening at 5 p.m. (Saturdays excepted). Special classes are held in bacteriology, diseases of the eye, throat, X rays, anæsthetics, intestinal surgery, tropical medicine, cystoscopy, operative surgery, &c.

Fees.—The fee for the hospital practice including all the ordinary lectures and demonstrations, is £1 1s. for one week; £2 2s. for one month; £5 5s. for three months; £8 8s. for six months; £12 12s. for one year, and £25 for a life ticket. A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £3 3s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery is £2 2s. A prospectus containing full particulars will be forwarded on application to Mr. L. A. Bidwell, Dean.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.—This post-graduate school is established in connection Prince of Wales's General Hospital, Tottenham, N., which is recognised by the University of London as a place of post-graduate study for the M.D. and M.S. degrees, and by the India Office for purposes of study leave. Facilities are here afforded to qualified medical practitioners for taking part in the work of an active general hospital, and for attending demonstrations of various branches of medicine surgery, and gynæcology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, skin, in fevers, psychological medicine, the administration of anæsthetics, radiography and dentistry. Cliniques, lectures and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week, except Saturday. Special classes, the attendance at which will be limited, are arranged in gynæcology, the surgical diseases of children, including orthopædic surgery, diseases of the throat, nose and ear, diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, analysis of gastric contents, clinical examination of the blood, diseases of the skin, abdominal surgery, radiography, bacteriology, and medical electricity. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of three guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may, for the present, be obtained on payment of a fee of 5 guineas. The opening lecture of the Winter Session will be given by Dr. W. Hale White, at 4 p.m., on Thursday, October, 3rd. Additional information with a syllabus of lectures, demonstrations, and special classes, may be obtained from the Dean of the Post-Graduate College, Dr. A. J. Whiting, 142 Harley Street, W.

LONDON POST-GRADUATE ASSOCIATION.—This Association offers facilities for Clinical Study to qualified medical men. Joint cards of admission are issued to the Clinical Instruction of the following General Hospitals and Schools of Medicine:—Charing Cross, Guy's, Westminster, St. Thomas's, University College, St. Mary's, King's College, besides several special hospitals. *Fee.*—For three months, 10 guineas; for six months, 15 guineas; and for any longer period at the further rate of 9 guineas for each additional six months. Further particulars may be obtained of the Secretary, London Post-Graduate Association, Examination Hall, London, W.C.

The following are the principal provincial hospitals having the greatest number of beds, to which students are admitted where clinical instruction can be obtained, but to which there is no medical school attached :—

BRADFORD INFIRMARY.—The hospital contains 220 beds. Non-resident pupils are received and abundance of clinical material is obtainable. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

LIVERPOOL NORTHERN HOSPITAL, which has recently been rebuilt, now contains 246 beds, and is completely equipped with the most modern appliances. Clinical instruction is given by the staff during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fees. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £6 6s.; three months, £4 4s.; practical pharmacy, £2 2s.

NORFOLK AND NORWICH HOSPITAL.—This hospital is recognised by the Colleges, and contains 220 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

NORTHAMPTON GENERAL HOSPITAL.—This hospital contains 174 beds; it has been recently enlarged and re-arranged. Non-resident pupils are received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10s.

ROYAL BERKSHIRE HOSPITAL.—The town of Reading, in which this hospital is situated, has a very large working-class population, and excellent opportunities for clinical instruction in the wards and extensive out-patient department are afforded here. It contains 160 beds, a splendid library, in which the Reading Pathological Society holds its mettings.

WOLVERHAMPTON GENERAL HOSPITAL.—The hospital contains 230 beds, attendance at this hospital being recognised by all the Examining Boards. Pupils are trained in clinical work by the medical and surgical staff. *Fees;* Six months, £6 6s.; twelve months, £12 12s.; perpetual, £21.

Ireland.

THE IRISH MEDICAL SYSTEM.

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any hospital is free to enter for the whole or any part of his course at any school or hospital he pleases.

COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student :—

COST OF MEDICAL EDUCATION.

School of Physic, Dub. Univ. ..	£122 6s. 6d.
Royal College of Surgeons School	£124 19s.
Catholic University School ..	£124 19s.
Queen's College	About £110

COST OF DIPLOMAS OR DEGREES.

Dublin University	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree).
Royal University	£15.
Conjoint Royal Colleges ..	£42.
Apothecaries' Hall	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £232 10s. 6d. according as the teaching of the Queen's Colleges and the degrees of the Royal University, or the teaching and degrees of Dublin University, are taken. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred the total will vary, say, from £170 to £200. "Grinding," although not officially recognised, occupies a position almost identical with that of the extra-mural instruction in other schools. Its cost must be reckoned among the expenses of the course, for, while not essential, it has become customary for almost all students to obtain aid in their studies in this way. As a rule, this private instruction costs about £5 5s. for each of the four examinations.

The above sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the needful information for his guidance if he likes to pay for his course in this fashion.

All the Dublin schools require fees to be paid in advance.

DATE OF ENTRY.

The entry of names and commencement of study in Ireland is *supposed* to date from the 1st of October in each year, but the session really dates from the 1st of November, and the entry of names may be delayed by the dilatory to the 25th of the same month. It should, however, be remembered that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses a fortnight at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of June.

PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin, unless, as is usually the case, this duty is undertaken for him by the school registrar. He is thereupon placed upon the Register of Medical Students (without fee), and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, *e.g.*, the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Examination passes in the required subjects, and all other examinations recognised by the General Medical Council are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows :—1. English language, including a specified author, dictation, grammar, and composition ; also parsing and analysis from a book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (*a*) arithmetic, including vulgar and decimal fractions ; (*b*) algebra, including simple equations ; (*c*) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects :—(*a*) Greek, (*b*) French, (*c*) German.

THE IRISH LICENSING BODIES.

The Medical Licensing Bodies of Ireland are four in number, and, as a rule, students gravitate into one or other of five classes :—*a.* Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. *b.* Those who take the licence of the conjoint Royal Colleges of Physicians and Surgeons. *c.* Those who take their qualifications at the Royal University of Ireland, where graduation in Arts is not necessary. *d.* Those who take the licence of the Apothecaries' Hall. *e.* Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences. Almost all these last-named emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomata, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

THE UNIVERSITY OF DUBLIN.

The University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their Arts degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to those who have held, or have been qualified to hold, for at least three years, the degree of M.B. and B.Ch. It does not grant degrees to any but full graduates in Arts, consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows :—Lectures, £67 4s. 0d. ; Hospitals, £55 13s. ; Degree Fees, £27.—Total, £149 17s. 0d.

The expense of the B.A. degree, amounting altogether to £83 4s., should be added, making the total cost £233 1s. 0d.

In addition to its ordinary qualifications the University grants the following higher degrees :—

Doctor of Medicine.—To obtain this the candidate must have obtained the degree of M.B., or have been qualified to have obtained it for three years. He must then read a thesis before the Regius Professor of Medicine. Fee for this degree, £13.

Master of Surgery.—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for this degree, £11.

Master in Obstetric Science.—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynæcology, anatomy of female pelvis and elementary embryology, and clinical gynæcology. Fee for this degree, £5.

Diplomate in Medicine, Surgery, and Midwifery — Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in medical studies. The medical course and examinations are the same as for the degrees, Fees for the diplomas in medicine, surgery, and midwifery, £21. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by paying the degree fees.

Diploma in Public Health.—The candidate must be an M.D. or a Graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge, must have completed, subsequent to registration, six months' practical instruction in a laboratory, and also have studied practically outdoor sanitary work for six months under an approved Officer of Health.

Degree and Licence in Dental Science.—Candidates for the degree in dental science must have taken a degree in Arts, and must have had their names in the books of the Medical School for five years. Two examinations must be passed—namely, the Previous Dental at the end of the second year, and the Final Dental at the end of the fifth year. Candidates for the Licence are required to matriculate in Arts, and pass one Term Examination. The course of study is the same as for the degree with the exception that no lectures in pathology or bacteriology are required. The total fees for the licence, including the premium for Dental Mechanics (£100), are £200 17s., while those for the degree are about £210, to which must be added the cost of the B.A. degree.

Post-Graduate Classes.—A short post-graduate course is now given annually in July in connection with Trinity College Medical School. It includes special work on Diseases of the Eye, Nose, and Throat, Gynæcology, Diseases of the Skin, X-ray work, Medicine, Surgery (clinical and operative), and Clinical Pathology.

Royal Services School.—The object of this school is to prepare candidates for the Indian Medical Service, and Royal Army Medical Service. It is conducted on a comprehensive scale, and affords special opportunities for operating on the cadaver, and for the study of commentaries. Two sessions are held yearly, each lasting for about ten weeks.

THE ROYAL UNIVERSITY OF IRELAND.

THE Royal University of Ireland is purely an examining body. Its degrees are granted on one year's acts, *i.e.*, the matriculation examination of this University and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, is about £125. Some of the Arts examinations are conducted, not only in Dublin, but at certain local centres.

The University confers the following medical degrees:—

M.B., B.Ch., B.A.O., and the higher degrees of M.D., M.Ch., and M.A.O. It also confers a Diploma in Public Health and a Diploma in Mental Diseases.

All degrees are open to persons of either sex who shall have passed the Senior Grade Examination of the Intermediate Education Board for Ireland in the subjects prescribed for the Matriculation Examination of the University, and who shall apply for exemption from the Matriculation Examination in the year in which he shall have passed such examination.

The University examinations are held in the spring, beginning about the middle of April, and in the autumn, beginning towards the close of September.

All candidates for any degree must pass the matriculation examination, or the Senior Grade Examination or the Intermediate Education Board (as above mentioned) and the first University examination.

The course for the degree of M.B., B.Ch., B.A.O., extends over five years.

Students will be admitted to the first University examination after one year from matriculation. Fee, £1.

The medical course consists of three previous examinations, one at the end of each year, and one degree examination at the end of the fifth year. Fee for each previous examination, £1; for the degree examination, £2; for the diploma, £10.

In addition, the following degrees are granted:—

Diploma in Public Health.—Conferred only on graduates in medicine of the University of at least twelve months' standing. Fee, £2. Subjects.—Meteorology, bacteriology, chemistry, physics, vital statistics, hygiene, sanitary engineering, architecture and law.

The M.D. Degree.—Conferred only on graduates in medicine of the University of three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination comprises medical diseases and the theory and practice of medicine, including pathology. Every candidate will be examined at the bedside, and be required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising therefrom. Fee, £5.

The M.Ch. Degree.—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. degree. The examination comprises surgery, both theoretical and operative; surgical anatomy; ophthalmology and otology. Fee, £5.

The M. A. O. Degree. — Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. and M.Ch. degrees. The examination comprises midwifery and diseases of women and children. Fee, £5.

Prizes, &c.—First Examination in Medicine. Two first-class exhibitions of £20 each, and two second of £10 each.

Second Examination in Medicine.—Two first-class exhibitions of £25, and two second-class of £15, and the Dr. Henry Hutchinson Stewart Medical Scholarships, value £10 a year for three years.

Third Examination in Medicine.—Two first-class exhibitions of £30 each, and two second of £20 each.

Medical Degrees Examination. At each of the two Examinations in the year three Exhibitions of £21 each in the groups of medicine, surgery and midwifery. One travelling medical scholarship of £100. One medical studentship of £200 per annum, tenable for two years.

The Dr. Henry Hutchinson Stewart Scholarship for proficiency in the Knowledge of Mental Diseases for competitions among medical graduates if not more than three years' standing. This Scholarship is of the annual value of £50, tenable for three years.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

These examinations are held conjointly by the two Colleges. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The curriculum has recently been revised, and made of a more practical nature. In common with the English Colleges, the subjects of the

First Professional examination may be studied either at a medical school or at an institution other than a medical school recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Physicians, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary; fourteen days' notice is required from candidates for the Professional examination.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The Conjoint Colleges also confer a diploma in Public Health, of which information will be found on page 280.

ROYAL COLLEGE OF PHYSICIANS.

This College issues a Licence in Medicine and a Licence in Midwifery to Registered Medical Practitioners.

Licence in Medicine.—The subjects of examination are:—Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene and Therapeutics.

Licence in Midwifery.—The subjects of examination are:—Gynæcology and Midwifery. A Registered Medical Practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the Licence to Practise Medicine £15 15s. Fee for the Licence to Practise Midwifery £5 5s.

Membership.—The Membership is open to University Graduates in Medicine and to Licentiates of the Royal Colleges of Physicians of the United Kingdom. The Examinations for Membership are held in January April, July, and October, and such other times as the President may appoint.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This College grants a licence in Surgery to registered medical practitioners. Candidates who hold registrable surgical diplomas, including the licence of the Apothecaries' Society of London, and the Apothecaries' Hall, Dublin, granted since October, 1886, are admitted to examination without further evidence of study, but candidates who hold medical qualifications only, including the L.S.A. and L.A.H., granted before October, 1886, will be required to produce certificates of two courses of lectures in anatomy and dissections, one course of practical histology, one course of lectures in surgery, and one course of operative surgery.

Candidates are examined in surgery, clinical and operative; surgical appliances; and ophthalmic surgery. The fee is £26 5s. The fee for a special examination is £31 10s.

A diploma in Midwifery is also granted after examination to registered medical practitioners. Candidates must produce evidence of (*a*) attendance on a course of lectures on midwifery and diseases of women and children in a recognised school; (*b*) attendance or six months' practice at a recognised lying-in hospital or recognised dispensary for lying-in women and children; and (*c*) of having conducted at least thirty labour cases. The fee for the examination is £15 15s.

Fellowship.—Candidates for the Fellowship of the College must enter their names with the Registrar at least a month before the date of examination, in order that the Council may decide whether to approve of the application. Examinations are held the third Mondays in February, May, and November. If the application is approved, the candidate will be admitted to the next sessional examination or to a special examination (except during the months of August and September) if granted by the Council. Candidates are divided into two grades:—

Grade 1.—Licentiates or graduates in surgery of less than ten years' standing.

Grade 2.—Licentiates or graduates in surgery of more than ten years' standing.

Students, not either Licentiates or Graduates in Surgery, are permitted to present themselves for the *Primary* Examination under Grade I.

Candidates in Grade 1 must pass two examinations—Primary (in anatomy and physiology) and Final (in surgery). Candidates in Grade 2 need pass but one examination in surgery, surgical anatomy, and surgical pathology.

Fees.—Grade 1.—For Licentiates of College; Primary examination, £15 15s.; Final examination, £10 10s. Licentiates in Surgery of other licensing bodies: Primary examination, £26 5s.; Final examination, £15 15s. Students of the College: Primary examination, £5 5s.; Final examination, £21. Students of other licensing bodies: Primary examination, £10 10s.; Final examination, £31 10s.

Grade 2.—Licentiates of the College, £26 5s.; Licentiates in Surgery of other licensing bodies, £42.

LICENCE IN DENTAL SURGERY.

There is probably no specialty in surgery which gives as great a number of its practitioners a living and the prospect of an income as dentistry. A young man who has got his diploma and knows something of his business, and is willing to attend to it, seldom fails to get a substantial foothold in Ireland in a few years. The University of Dublin grants both a Degree and a Licence in dental surgery. To obtain the former, candidates must have taken a degree in arts; the licence is obtainable by all duly qualified persons who have passed the Public Entrance Examination of Trinity College, Dublin. The Royal College of Surgeons in Ireland grants a Licence in Dentistry.

Course of Study for the Licence in Dentistry.—Candidates are required to pass three examinations, *viz.*:—Preliminary (in General Education), Primary Dental, and Final Dental.

All information concerning this licence may be obtained from the Registrar of the College. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The subjects of examinations include physics, chemistry (including metallurgy), anatomy, physiology and histology, and surgery. The fees for the primary Dental Examination amount to £10 10s; and for re-examination, if rejected, £5 5s. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are examined in dental surgery, theoretical (including dental pathology), clinical, and operative; and in dental mechanics, theoretical, clinical, and practical (including the metallurgy of the workshop). Candidates must pass in all the subjects at the same time.

The fees for the Final Dental Examination in the case of candidates holding the L.R.C.S.I., or students who have passed the Primary Dental or Third Professional Examination of the College, £10 10s.; re-examination, £5 5s. The fees for Final Examination of all other candidates, £26 5s., and for re-examination, £10 10s. The extra fee for Special Examination, £5 5s. A rejected candidate will not be again admitted to examination until after a period of three months.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum, and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, and he also possesses the privileges of an apothecary.

There are four professional examinations, the total fees for which amount to 21 guineas. Women are eligible for the diploma.

Registered Medical Practitioners will receive the diploma of the Hall upon passing an examination in the subject or subjects not covered by their previous qualification, and on paying a fee of ten guineas; if medicine or surgery is required, five guineas extra will be charged.

The fees payable for each examination are as follows: First Professional, £5 5s.; Second, £5 5s.; Third, £5 5s.; Final Examination, £6 6s.

A candidate is allowed for each professional examination which he has completed at any other licensing body, except the Final. If he has passed only in some of the subjects in a given examination, he has to pay the whole of the fee for that examination.

The fees for re-examination are: For each subject, £1 1s., excepting in the subjects of chemistry, pharmacy, surgery, medicine, second anatomy, physiology, pathology, and ophthalmology, the fees for which are £2 2s. each.

The fee for the Third and Final, or Final alone, is £15 15s., when the other examinations have been taken elsewhere.

All examination fees are to be lodged in the Sackville Street Branch of the Royal Bank of Ireland to the credit of the Examination Committee.

Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40 Mary Street, Dublin, at least fourteen clear days before the day of examination.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries' Hall of Ireland, must, before proceeding to the Final Examination, produce evidence of having been registered as medical students for fifty-seven months; also of having attended courses of instruction as follows:

One course each (winter course of six months) of the following: Anatomy (lectures), chemistry (theoretical), midwifery, practice of medicine, physiology and surgery. Dissections, two courses of six months each. Courses of three months.—Materia medica, medical jurisprudence, chemistry (practical), practical physiology and histology, operative surgery, physics, clinical ophthalmology, biology, clinical instruction in mental disease, pathology, and a course in vaccination.

Medico-Chirurgical Hospital, twenty-seven months to be distributed over the last four years of study. The candidate may substitute for nine months in this, hospital attendance six months as a resident pupil.

Three months' study of fever.

Six months' practical midwifery and diseases of women.

Three months' practical pharmacy in a recognised clinical hospital or a recognized school of pharmacy, or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council, and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than fifteen days prior to such registration, except in the subjects of physics and biology. This registration is not undertaken by the Hall.

The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar, at 40 Mary Street, Dublin.

THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the Royal University, and the Conjoint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in:—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Sanitary law and vital statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or a medical officer of health who is a teacher in Public Health of a recognised medical school."

In addition to taking the prescribed course a candidate for the D.P.H. of the University of Dublin must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge, and his name must have been on the "Medical Register" for at least twelve months before the examination. The Royal University only confers its diploma on its own graduates.

THE DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Royal University of Ireland grants a diploma for proficiency in the treatment of mental diseases under the following conditions:—

The diploma is conferred only on graduates in medicine of the University. Candidates must give notice, in writing, to the secretaries of their intention to present themselves, and must pay the prescribed fee of £2 at least one month previous to the examination. Candidates who satisfy the examiners will be required to pay a further fee of £3 before the diploma is conferred The subjects for this examination are those required by the Hutchinson Stewart Scholarship for proficiency in the treatment of mental diseases.

THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows:—

The School of Physic of Dublin University.—This school is formed by an amalgamation of the School of Trinity College and of the College of Physicians.

Every student of the school must be matriculated by the Senior Lecturer, for which a fee of 5s. is payable, but he need not attend any of the Arts course unless he desires to obtain a University licence or degree in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the Entrance and a Term examinations of the University, of the Royal University, of the College of Surgeons, or some other examination recognised by the General Medical Council.

Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June; one scholarship is given in anatomy and institutes of medicine; the other in zoology, chemistry, botany, and experimental physics.

A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery, as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Final Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him within two years from the time of obtaining the prize.

The Sir John Banks Medal and Prize, founded by Sir J. Banks, M.D., formerly Regius Professor of Physics, are awarded both for best and second best answers at the Medical Travelling Prize Examination.

The Edward Hallaran Bennett Medal, founded by pupils of the late Dr. E. H. Bennett, formerly Professor of Surgery, is awarded to the Surgical Travelling Prizeman.

Class prizes are given at the end of the session of between £5 and £10 in value.

The John Mallet Purser Medal, founded by Prof. Purser's past pupils, is awarded annually to the student who, at the ordinary June Intermediate Medical Examination, Part I., in Anatomy and Institutes of Medicine, shall obtain highest marks in Physiology and Histology, provided that he passes the examination in full.

Fitz-Patrick Scholarship.—This scholarship consists of the interest on £1,000. It will be awarded annually to the student who obtains the highest aggregate marks at the five sections of the Final Examinations, provided that he has completed his medical course in the prescribed period of five years.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND. SCHOOLS OF SURGERY.—These schools are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for over a century. They are carried on within the College buildings, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors, and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories fitted with the most approved appliances, in order that students may have the advantage of the most modern methods of instruction. A refreshment room is now open, where students can have luncheon. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes, and lighted throughout by the electric light.

All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

All the diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

Prizes.—The Barker Prize, £31 10s.; the Carmichael Scholarship, £15; the Mayne Scholarship, £8. The Gold and Silver Medals in Surgery and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by medals if sufficient merit is shown, will also be given in each subject. Prospectus and Student's Guide can be obtained on written application to the Registrar, Royal College of Surgeons, Dublin.

Two short post graduate courses are held in the year. Full particulars can be obtained from the Registrar.

THE CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, Dame Street. It prepares students for all medical examinations, particularly those of the Irish Colleges of Physicians and Surgeons, and the Royal University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories, including those for the study of bacteriology and public health, have been added. The institution has also been recently chartered, under the Educational Endowment (Ireland) Act, and it is now controlled by a Board of Governors. The total fees for school and hospital courses is £160, payable as the courses are taken out.

The following Exhibitions are awarded annually:—Two first year's, value £12 10s. each; two second year's, value £10 each; one third year's Royal Exhibition of £12 10s.; one final Conjoint Colleges Exhibition of £12 10s.; two large gold medals, besides several other class medals.

A Guide for Medical Students, which gives all the information required by parents, and by students who desire to join the medical profession, may be obtained free on application to the Registrar.

THE QUEEN'S COLLEGES—BELFAST, CORK, AND GALWAY.

These three important academic institutions educate students for all colleges and degrees, and are maintained, as hitherto, by a Government grant. The same curriculum as that formerly adopted is continued, and the various exhibitions and scholarships are still available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The colleges are well adapted for high-class technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in three-fourths of a course. The scholarship examinations are held in October.

QUEEN'S COLLEGE, BELFAST.

The total cost of the medical curriculum of the Royal University of Ireland, including examination fees and perpetual fee for the Royal Hospital, but not including fees for the special hospitals, is about £95. If the Conjoint Examination of the Royal Colleges is taken the expense is almost the same.

Clinical instruction is given at the Royal Victoria Hospital. The Union and Fever Hospitals, the Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, and the District Lunatic Asylum are also open to students.

Prizes.—(1) Ten medical scholarships each year, value £20 each; (2) two Dunville studentships (one each year), value £150 each; (3) one Andrews studentship each alternate year, value £140; (4) numerous sessional prizes. A Mackay Wilson Travelling Medical Scholarship will be awarded in 1909.

During the summer session special classes are formed in bacteriology and clinical pathology, and during the winter facilities are afforded to medical men to work at these subjects in the pathological laboratories. From time to time lectures and demonstrations are given in the anatomical department on the Advanced Anatomy of the Nervous System, or some other department of applied anatomy.

A pamphlet containing full information can be had on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE, CORK.

The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the Royal University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries Hall of Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the college are also accepted by the University of Cambridge. The total fees for the college lectures and Hospital attendances required by the Royal University of Ireland is about £85.

Clinical instruction is given at the North and South Infirmaries. Students can also attend the Mercy Hospital, the Cork Union Hospital, the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences on October 21st, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

Scholarships and Prizes.—Eight medical scholarships, two in each of the first four years, of the value of £25 each, and in the fifth year the Blaney Scholarship of the value of about £32, and a Senior Exhibition, value £30. Three Exhibitions, one in practical medicine, one in practical surgery, and one in practical midwifery, each of the value of £15. Book prizes at the sessional examinations.

Further information can be obtained in the College Regulations, or on application to the Registrar, Queen's College, Cork.

QUEEN'S COLLEGE, GALWAY.

Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament (1892). The Galway Fever Hospital and Galway Throat Hospital are also open to students. The medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom.

Prizes.—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject. A Senior Scholarship in Anatomy, value £40, the holder of which is usually appointed Demonstrator, is offered annually for competition, tenable for one year by a student who shall have attended the Medical School of the College for at least two sessions, and shall have obtained a Degree in Arts or Medicine, or a Diploma in Medicine, from a Licensing Body. Scholarship examinations are held at the commencement, and those for Sessional Prizes at the close, of each session.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

The Pharmaceutical Society of Ireland issue two qualifications and a certificate. The qualification of Registered Druggist; the qualification of Pharmaceutical Chemist; and the certificate of competency as Assistant to a Pharmaceutical Chemist.

Registered Druggist.—This qualification entitles the holder to keep open shop for the selling, retailing, and mixing of poisons. In order to obtain it, a person must now have served an apprenticeship or assistantship of four years to an apothecary, pharmaceutical chemist, or to a person who was, or would have been entitled to become, a registered chemist and druggist or a registered druggist, and be 21 years of age. He shall be examined with respect to his knowledge of English orthography and composition, arithmetic, and the weights and measures of the British Pharmacopœia, the appearance and properties of the various drugs and chemicals in general use, and as to the provisions of the Poisons Act. The fee is four guineas.

Examinations in Dublin (also in Belfast and Cork or other place if 12 candidates offer) on the second Tuesday of January, April, July, and October.

Pharmaceutical Chemist.—The qualification of a pharmaceutical chemist in Ireland confers greater privileges than is the case in England.

The subjects of examination are divided between the "Preliminary" and the "Licence."

The Preliminary examination is held on the first Thursday and following day of January, April, July, and October.

The fee is £2 2s. for the first attempt, and 10s. 6d. for each subsequent examination. Further particulars with reference to the subjects for examination may be obtained from the Registrar. The British Society's examination is accepted in lieu of this, as well as those recognised by the General Medical Council as a preliminary to medical studies.

Pharmaceutical Licence Examination.—This examination confers the title of Pharmaceutical Chemist and the right to compound medical prescriptions. Candidates must be 21 years of age, and must have passed the Preliminary prior to the service at practical pharmacy, unless such service was commenced before 1st January, 1907. They must, unless having passed the Preliminary previous to 1884, produce certificates of having served four years as assistant or apprentice to an apothecary or pharmaceutical chemist or four years to a druggist, two years to an apothecary or pharmaceutical chemist, also a certificate of having attended a course of practical chemistry of not less than three months' duration, and of having actually worked at the bench for 100 hours during the said course at a recognised school; and also a course of botany and materia medica. The fee for examination is five guineas, and for re-examination two guineas. Examinations are held in Dublin on the second Wednesday and following day of January, April, July, and October.

Assistant to a Pharmaceutical Chemist.—The examination for the certificate of competency as an assistant may be described, in brief, as the same as that for the Licence, minus the examination in chemistry and botany, with the fee reduced to one guinea (half a guinea on the second and subsequent attempts). The Preliminary examination must be passed as for the Licence, and the usual 14 days' notice must be given. Candidates must have been engaged in practical pharmacy for four years.

Examinations are held on the Monday following the pharmaceutical Licence examination or on such days as the Council may direct.

DEPARTMENT OF AGRICULTURE AND TECHNICAL INSTRUCTION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE FOR IRELAND.

SESSION 1907—1908

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of agriculture, chemical manufactures, engineering, physics, and natural science. A diploma of Associate of the College is granted at the end of the three years' course. Non-associate students may join for any course required. There are several entrance scholarships, (*a*) in agriculture, and (*b*) in science and technology, tenable for three years, of the value of £50 each yearly, with free tuition. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable for two years. Two are competed for by the first year associate students at the end of each session. All the laboratories and drawing schools are open daily for practical instruction. The Session commences on Tuesday, October 1st, 1907.

The courses of chemistry, physics, botany, geology, and mineralogy and zoology are recognised by the Royal University of Ireland, and certificates of attendance are granted to medical and other students attending these courses, as also the courses of the chemical, physical, zoological, botanical, and geological laboratories.

The Entrance and Science Scholarship Examinations are held during the first week in July, and the Examinations for Agricultural Scholarships in the first week in September.

THE DUBLIN HOSPITALS.

THE clinical hospitals in Dublin are ten in number exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopædic hospital, a fever hospital, an ophthalmic hospital with two centres, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospitals for twenty-seven months, *i.e.*, three winter sessions of six months and three summers of three months, with the five years of study. The fee at all general hospitals is £8 8s. in winter, and for the summer £6 6s., or £12 12s. for the entire session of nine months if taken together.

GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—The accommodation at these hospitals is as follows:—Hardwicke Hospital, 120 beds; Whitworth Hospital, 64 beds; Richmond Hospital, 86 beds—total, 270 beds. These hospitals are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Instruction is also given on various special branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are large ophthalmic, aural, throat, and gynæcological dispensaries, and instruction in these important subjects is given. Twelve resident clinical clerks are appointed each quarter, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, but also to those who ar qualified in medicine and surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected every six months, and receive a salary. The Richmond Lunatic Asylum, containing 1,600 beds, adjoins these hospitals.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates of this hospital are recognised by all the Universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every three months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. William Taylor, F.R.C.S., 47, Fitzwilliam Square, Dublin.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and also wards for infants and children. Operations are performed, except in cases of urgency, at 10 a.m. on Tuesday, Thursday, and Saturday. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope; also special instruction is given on practical pathology and X-ray photography. Two House Surgeons are elected annually and three resident pupils half-yearly. Prize examinations, including examinations for the Hudson Scholarship, £30 and a gold medal, and a senior prize of £10 and a silver medal, in addition to surgical and medical prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Mr. Heuston, F.R.C.S.I., 15, St. Stephen's Green North.

THE ROYAL CITY OF DUBLIN HOSPITAL.—This hospital has recently been enlarged and improved to a very considerable extent. A special course of instruction is given on ophthalmic and aural disease. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anæsthetic room have been constructed in accordance with the most modern surgical requirements. A Röntgen-ray and light treatment of lupus department has recently been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Special classes for first year students. Full particulars can be had on application to Mr. G. Jameson Johnston, M.B., F.R.C.S.I., Hon. Sec. Med. Board.

SIR PATRICK DUN'S HOSPITAL is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It is officered almost exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now free to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in the wards during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given the members of the hospital class of seeing the various applications of the X-rays to the diagnosis and treatment of injury and disease.

MATER MISERICORDIÆ HOSPITAL.—This hospital, containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. A course of lectures and instruction on fever will be given during the winter and summer sessions. A certificate of attendance upon this course to meet the requirements of the various licensing bodies may be obtained. Opportunities are afforded for the study of the diseases of women in the wards under the care of the obstetric physician, and at the dispensary, held on Tuesdays and Saturdays. Lectures on clinical gynæcology will be delivered on Saturdays at 11 a.m. Ophthalmic surgery will be taught in the special wards and dispensary. A special course of instruction in pathology and bacteriology, as applied to medicine, will be given. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general, medical and surgical diseases, accidents, &c. Leonard Prizes: One gold and one silver medal will be offered for competition annually in the subject of medicine, and one gold and one silver medal in the subject of surgery. Junior Leonard Prizes: Two prizes of the value of £3 and two prizes of the value of £2 will be offered for competition in medicine and surgery respectively.

MERCER'S HOSPITAL.—This hospital, founded in 1707, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of resident pupil, &c. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. R. Charles B. Maunsell, M.B., F.R.C.S., 32 Lower Baggot Street, Dublin.

ST. VINCENT'S HOSPITAL was established in 1834, it has 160 beds, and in connection with it there is a largely-attended dispensary, a convalescent home, and a nurses' institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospitals. The resident officers consist of a house surgeon, a house physician, and four resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session. A prospectus can be had from Dr. Dargan, 45, Stephen's Green, East Dublin.

DR. STEEVENS' HOSPITAL, situated at Kingsbridge, is the oldest and one of the largest clinical hospitals in Dublin, and contains over 200 beds. A very fine Nurses' Home was recently added to the institution, with accommodation for over seventy nurses. A new and thoroughly equipped dispensary and out-patient department has been completed and opened to patients. There is accommodation for twelve resident pupils—four medical, six surgical, and two in the special departments, each of whom is supplied with a separate room. All information with regard to these appointments can be had from the Resident Medical Officer at the hospital. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while the special ward for venereal diseases affords exceptional opportunities for the study of this important subject.

Jervis Street Hospital is the oldest established in Dublin. The new hospital was completed in 1896, since which time it has been open for the reception of patients. In addition to large medical and surgical dispensaries, the out-patient department includes special departments for the treatment of diseases of the skin, eye, ear, and throat, and diseases peculiar to women. Two resident surgeons are appointed annually. Clinical clerks and surgeons' dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve interns are appointed annually, and are provided with apartments, &c., free of expense. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons.

Students of Jervis Street Hospital are entitled to attend free of charge the Children's Hospital, Temple Street, which contains 100 beds, and where special lectures are given on Diseases of Infancy and Childhood, and on Orthopædic Surgery and appliances, and to obtain special courses in fevers at Cork Street Fever Hospital.

Students of other Hospitals are admitted as residents when vacancies occur.

Terms: £2 2s. per month, or £5 5s. for three months, exclusive of board.

SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in-Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital), the Dental Hospital, the Throat Hospital, the Orthopædic Hospital, the Children's Hospitals in Harcourt Street and in Temple Street, and the City Hospital for Diseases of the Skin.

The Rotunda Hospital.—This institution is the largest, the longest established, and the most famous gynæcological as well as maternity hospital in the British Empire. The work performed by it is about three times greater than that of any other hospital of its kind in Ireland. The number of patients admitted to the hospital, and also attended in the extern maternity has increased enormously within recent years. The routine daily work comprises the attendance of lectures on midwifery and gynæcology; practice in abdominal palpation; personal conduction of parturition both in the extern and the intern maternities; cystoscopic examinations, as well as attendance at the operation work of the hospital. The hospital affords exceptional advantages to qualified men who take out a three months' course during the autumn, winter, and spring months, for they (if considered competent) are permitted a certain amount of practical operation work, viz.—forceps, curettings, perineorrhaphy, &c. Students are liable to summary dismissal without refund of fees for gross misconduct, or serious breach of the hospital rules. A special afternoon class in gynæcology is held by the Senior Assistant, £2 2s. per month. The Pathological laboratory under the direction of Dr. Rowlette has become an important feature of the hospital. Students can enter at any time for periods of one month or longer. Certificates of attendance are accepted by all the licensing bodies. The L.M. certificate is obtained by attendance at the hospital for six months, with the subsequent passing of an examination. A special certificate in gynæcology is presented to students whose work meets with the Master's approval. Paid clinical assistants are selected (from among those who have obtained the hospital L.M. certificate) by competitive examination, for periods of six months. The residents' quarters have undergone complete renovation and now afford comfortable accommodation. The grounds of the hospital contain asphalt and grass courts for lawn tennis and croquet. There is also a full-size billiard table.

Fees for Pupils.—Intern:—One month, £6 6s.; two months, £9 9s.; three months, £12 12s.; six months, £21; single months other than the first, £4 4s; board and lodging in the house per week, £1 5s. Night students (not resident in house), £6 6s. for first three months; £4 4s. for the second three months. For further particulars apply to E. Hastings Tweedy, Master, Rotunda Hospital, Dublin.

Coombe Lying-in Hospital.—This hospital consists of two divisions, one of which is devoted to lying-in cases, and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland; nearly 18,000 cases are treated annually, either as intern or extern patients. Lectures are delivered, practical instruction is given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the diseases of women and children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. This is the largest dispensary of its kind in Dublin. There is no extra charge for attendance at this dispensary. There is accommodation for a number of qualified and unqualified intern pupils, who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. Clinical assistants are appointed from among the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. The residents' quarters have been much enlarged. A billiard table has been erected for the use of students. Extern pupils pay, for full course of six months, £8 8s. Intern pupils pay one month, £4 4s.; six months, £18 18s. Board and lodging in the hospital, 18s. per week. Lady students' intern pay for one month, £5 5s.; each consecutive month, £4 4s.

* **National Maternity Hospital.**—This institution, under the mastership of Dr. Barry and Dr. A. Horne, is situated in Holles Street.

Cork Street Fever Hospital is the only special fever hospital in Dublin. It is supported mainly by subscriptions, an annual Government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer sessions to those who desire a special course in fevers. There are also courses for the Diploma in Public Health. All particulars may be obtained on application to the Medical Superintendent.

The National Children's Hospital for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, is capable of containing 50 beds for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Sir Lambert H. Ormsby, F.R.C.S.I.

***The Children's Hospital, Dublin** (under the care of the Sisters of Charity).—This institution is one of the most progressive and up-to-date children's hospitals in the Kingdom, besides being the largest in Ireland. There are 100 beds available for patients; about 1,000 cases are admitted to the wards annually; and about 7,000 or 8,000 seen in the dispensary. During the last year a new operating theatre has been opened. It is fitted and furnished in the best possible fashion for present-day surgery. Special attention is given to orthopædic surgery, and the number of deformities from all parts of Ireland treated and cured in the hospital is rapidly increasing. A special masseuse has been appointed to the hospital to aid in this department.

The hospital is recognised for clinical instruction in the diseases of children by the R.U.I. and licensing bodies, which require a certificate of instruction in this important branch of medical education. A nursing home is in connection with the institution, and trained nurses are always available for private cases. Senior students or others requiring a post-graduate course at the hospital should apply for full particulars to M. C. Staunton, hon. sec., or to any member of the staff.

The Incorporated Orthopædic Hospital, Ireland.—This hospital was founded in 1876, and contains 80 beds. It is available for every class of deformity available for treatment. Particulars may be obtained from Captain Borthistle, Registrar, at the hospital.

The Royal Victoria Eye and Ear Hospital, Adelaide Road, Dublin.—This hospital, which was opened in March, 1904, is an amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Infirmary. The hospital contains 80 beds. Clinical instruction in diseases of the eye and ear, including the use of the ophthalmoscope and operations, is given daily from 10 till 1. Special classes for practical instruction in the use of ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time.

The Incorporated Dental Hospital, Lincoln Place.—This hospital, recently erected, is the only special Dental Hospital in Dublin. It is officered by a very strong staff of the leading dental surgeons of Dublin, and has a large *clientèle* and extensive practice among the Dublin poor. The fees are £15 15s. for the first year's study, and £12 12s. for second, and proportionately smaller fees for shorter periods.

The City Hospital for Diseases of the Skin and Cancer, Great Brunswick Street.—The first and only one of its kind in the city was the first in Ireland to instal the Finsen treatment. Senior students are admitted free to the practice of this hospital, which has a large daily out-patient attendance, with 15 beds available for the admission of acute cases. Classes of instruction will be given at regular intervals during the winter and summer sessions in the use of the Finsen light, X-rays, high frequency currents and radium, with demonstrations on (1) the production and use of the Röntgen rays, (2) electric currents, direct and alternating, with description of resistances, rectifiers and transformers; (3) accumulators, their construction, use, and methods in charging; (4) vacuum tube, choice of tube for particular kinds of work. Fluorescent screen, and how to localise foreign bodies.

BELFAST HOSPITALS.

* Hospital for Sick Children, Queen Street.—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879. The hospital consists of a medical ward with twenty-eight beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and not suffering from contagious disease, are admissible as in-patients. A very large extern is conducted in the out-patient department between the hours of 9 and 10 a.m., where children from birth to 14 years are attended to. The convalescent home, which is situated at Newtownbreda, contains thirteen cots, and its situation and equipment render it an admirable adjunct to the after-treatment of the cases admitted to the hospital. During the winter session systematic courses of lectures and demonstrations in the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Friday of each week at 9 a.m.

* Mater Infirmorum Hospital.—Established 1883. 160 beds. The New Mater Hospital, which was erected at a cost of over £50,000, was formally opened on April 23rd, 1900. During the year the intern patients numbered 1,525; accidents, 3,762, and cases treated in the Dispensary, 22,597; 389 surgical operations were performed with the most satisfactory results. The total number of patients who received treatment was 27,884, being an increase of 1,517 as compared with the year 1904. A notable feature is in the number of accident cases, as the hospital is conveniently situated in proximity to a large working-class population, and within easy reach of most of the public works.

The Belfast Maternity Hospital (Incorporated).—Established 1794. 30 beds.—The practice of the Maternity Hospital, the certificate of which is recognised by the Royal University, &c., &c., is open to students. The fee for the session is £2 2s. Resident nurses are also received for training for a period of six months, and a diploma given which is recognised by public bodies. Conditions for such on application to the Matron. During the year 1906, 373 patients were treated in the hospital, and 310 patients at their own homes. Besides this, 177 patients were dealt with in the extern gynæcological department. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff, on or before November 1st and May 1st.

Note.—Hospital was rebuilt in 1904 and removed to splendidly equipped new premises in Townsend Street. A Resident Surgeon elected periodically.

Ophthalmic Institution and Eye and Ear Hospital, Great Victoria Street, Belfast.—Established 1844. New hospital erected, 1867. New extern department and operation theatre added, 1902. This hospital is situated on the main road between Queen's College and the Royal Victoria Hospital. It contains about 30 beds for intern patients, and a large extern department. The latter is open on Monday, Wednesday and Friday at noon for eye cases, and on Monday and Thursday at noon for ear and throat cases. Special courses of instruction are given during the winter and summer sessions, but students can enter at any time, and can always obtain plenty of practice in ophthalmoscopic work. Full particulars may be had from Dr. Cecil Shaw, 18 College Square East, Belfast.

Royal Victoria Hospital.—Established 1791; incorporated by Royal Charter, 1875 and 1898. New hospital opened, September 17th, 1903. 300 beds; Convalescent hospital, 24 beds; Children's Hospital, 33 beds; Consumptive Hospital, 10 beds.

Ulster Eye, Ear, and Throat Hospital.—Established 1871. New hospital opened 1874. 30 beds.

Ulster Hospital for Children and Women, Mountpottinger, Belfast, is the only hospital in the large part of the city situated on the County Down side of the river. It is placed in a working class district, and has a great field for its charitable operations. There are in the hospital about twenty-two beds for children and eight for women. There is an extern department for children open every week-day, except Saturday, from 9 till 10, and for women at 11.30, and a special department for diseases of the eye, ear, and throat on Tuesdays and Fridays from 9 till 10. During the summer and winter sessions, clinical instruction is given to students daily, operations being chiefly performed on Wednesday and Saturday. There is a resident midwife for extern work, and every facility is afforded students for attending their cases in the district.

CORK HOSPITALS.

Victoria Hospital for Women and Children.—Established 1874. 70 beds. An immense amount of work is done in this hospital to relieve the poor of Cork, Kerry, and other counties. A large number of successful operations are done every year. The hospital contains several very fine private rooms for paying patients.

* County and City of Cork Lying-in Hospital.—Established 1798. 17 beds.

* Eye, Ear, and Throat Hospital, Western Road.—Incorporated 1898. 35 beds. Inpatients treated during year, 454; outpatients, 4,238. Clinical In-

struction is given during college session. Special demonstrations in the use of the ophthalmoscope, larynogscope, &c., are given from time to time.

* **Fever Hospital and House of Recovery.**—Established 1801. 110 beds.

* **Maternity.**—Established 1872.

* **Mercy Hospital.**—Established 1857. 80 beds.

* **North Charitable Infirmary.**—Established 1774 110 beds. Special wards for treatment of diseases of women and children. The extern department is largely availed of, and the number of accidents treated is very large. Clinical instruction is given daily from 9.30 a.m. to 12 noon. A new and thoroughly up-to-date operating theatre has recently been added at enormous expense.

Cork South Infirmary and County Hospital.—Founded 1773. The hospital contains 100 beds, available for clinical instruction, 40 medical and 60 surgical. There are also special wards devoted to the treatment of diseases peculiar to women and children, and a large medical and surgical extern department.

Clinical instruction is given daily during the session from 9.30 to 11.30, in both the medical and surgical wards, and clinical lectures are regularly delivered.

The operation and sterilising rooms are thoroughly up to date. The X-ray department is fully equipped with the newest apparatus necessary for such work. Students are regularly instructed in the methods of using the rays by practical demonstration on the cases requiring their use.

The hospital has been largely availed of by students of the Cork School of Medicine.

GALWAY HOSPITALS.

* **County Hospital.**—Established 1786. 60 beds.

* No answer to our request for information received from these hospitals.

IRISH PUBLIC SERVICES.

The Poor-law Medical Service.

For several years past the unsatisfactory nature of the Irish Poor-law Medical Service, as a career for young practitioners, has furnished a theme for the opening addresses at all the leading medical schools. In addition to the petty annoyances, the laborious and harassing duties, and the ever-increasing amount of clerical work which the new orders of the Local Government Board impose from time to time, the unfortunate medical officers are grievously underpaid, their salaries being totally out of proportion to the duties discharged, and in the majority of rural districts barely sufficent to cover the out-of-pocket expenses, such as are incurred in the keep of a horse and man, and other servants. The Local Government Board have recently laid it down, moreover, that the dispensary patients have the first call on the time of the medical officer, and that, even if he is engaged on an urgent private case, he must give it up and go off to attend on a scarlet-runner, as the dispensary visiting tickets are not inappropriately called. So strictly is he bound up to the discharge of his duties that unless incapacitated by sickness or other cause, or with the permission of the guardians expressly granted, he cannot leave his district for a single day, even if he makes provision for the performance of his duties in his absence by a brother practitioner. The Irish Medical Association, whose work includes the safeguarding of the interests and the improvement of the condition of the Poor-law medical officer, considers it an imperative duty to point out to young practitioners the following facts: (1) That the Poor-law Medical Service is one in which there is no promotion. (2) That it is a service where few facilities exist for original research, and still less for further medical culture, especially in the rural districts. (3) That, while medical education has become wider in its requirements, and more costly and difficult to procure, almost the same rate of payment given to less educated men forty years ago is still offered, and this, too, at a time when the rural prosperity of the country is less, and consequently lucrative private practice more difficult to obtain. (4) That there is no compulsory superannuation, and, as a consequence, many old and infirm doctors are forced to remain on in the service long after they have become unfit to discharge the duties, seeing nothing but extreme poverty and perhaps the workhouse itself staring them in the face.

We need go no further than to say that the Irish Poor-law Medical Service is a service to avoid. We therefore strongly urge on young medical men the importance of supporting the interest of the profession by refraining from applying for vacant posts of which the salary is insufficient, from accepting posts as *locum tenens* at a lower rate than £4 4s. per week.

There are 159 workhouses and about 810 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The salary in this service used to average about £114, but is rapidly coming down, and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep one or more horses, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments.

The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act, passed in 1873 and amended in 1878. The former office, in country districts, yields between £5 and £10 a year. and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who wishes to come. For each patient a fee of 2s. is paid, along with his salary, by the guardians, and the sum total of those fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10.

Qualifications.—The qualifications required by the Local Government Board are a licence in surgery, in medicine, and in midwifery; but registration in the "Medical Register," if effected since the passing of the Medical Act, in 1886, fulfils all requirements. The candidate must also be 23 years of age.

Duties.—The duty of the dispensary doctor is two-fold. He has to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have, perhaps, to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a guardian, warden, or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the case. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in many districts he has to make up all the medicines for the poor.

Workhouse Hospitals.—The number of unions in Ireland is 159, to each of which is attached a medical officer, who is appointed and controlled by the board of guardians in the same manner as the dispensary medical officer. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or long journeys across the country are involved.

The Irish Lunacy Service.

This service, at present, affords a comfortable livelihood for 22 Resident Medical Superintendents and 32 Assistants. The Superintendents receive salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the Assistants receive salaries and emoluments averaging about £200 a year. There are also Visiting Physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The Superintendents and Assistants must devote their whole time to their duties.

Heretofore the appointments of Medical Superintendents have been in the patronage of the Lord Lieutenant, but, under the Local Government Act, they are in the hands of the County Councils, with the proviso that no one shall be appointed who is not a fully registered practitioner with five years' service as Assistant. The Assistant is appointed by the Committee of the County Council to which the management of the the asylum is entrusted. In addition to these officers, there are, in certain larger asylums, Clinical Residents, who receive about £50 a year and full allowances. These appointments afford excellent introduction to the higher places in the service.

OTHER APPOINTMENTS.

There are, in addition to those which we have mentioned, certain appointments open to medical practitioners in special localities. They are :—

(1) Attendance on the Royal Irish Constabulary. (2) Attendance on the Coastguards. (3) Factory Surgeoncies. (4) Attendance upon the depôt soldiers who are not otherwise provided for.

The Constabulary are paid for at the rate of 2s. per month for each member of the force on duty in the district, including the wives and children of the men, but not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of the Royal Irish Constabulary, who usually acts upon the advice of the local District Inspectors as to the convenience of the men, and, of course, the emoluments depend on the number of Constabulary stations and the number of men in each.

The Coastguard Service.—The duty of the Medical Officer is to attend the men when sick and to examine candidates either for admission or for superannuation. The fees vary from 5s. to 2s. 6d. per visit. The appointments rest with the Admiralty, but are usually secured for the local Poor-law Medical Officer. The emoluments depend on the number of stations and men.

Factory surgeoncies are in the gift of the Chief Inspector of Factories in Whitehall. There is a set scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to, and, in some districts, at all events, the emolument is a matter of arrangement. The amount depends upon the size of the factory, the position being, in Dublin or Belfast, or in other large manufacturing centres, a lucrative one, but in other places scarcely worth taking. The attendance on the military depôts is not worth mentioning.

Death of Mr. Timothy Holmes.

THE death of Mr. Timothy Holmes, F.R.C.S., will form a matter of regret to all old Cambridge and St. George's men, as well as to a large circle of other members of the profession. Mr. Holmes, who was over eighty years of age, graduated as Bachelor of Arts, at Cambridge, as far back as 1847, and afterwards entered as a student at St. George's. He became a Fellow of the Royal College of Surgeons in 1853, and was soon afterwards appointed assistant surgeon to the hospital. He was for a long period full surgeon, and on retirement he was appointed consulting surgeon and joint-treasurer. For many years he was chief surgeon to the Metropolitan Police, and he had been president of the Royal Medical and Chirurgical and of the Pathological Society, as also vice-president of the Royal College of Surgeons, and Hunterian Professor of Surgery and Pathology to the College. His surgical writings have been numerous and valuable, including, besides many detached papers and articles, important contributions to a "System of Surgery," of which he was editor.

Scotland.

NOTWITHSTANDING the increased competition which the recent vigorous growth of the great English provincial medical schools, added to the unsurpassed attractions of the historic Metropolitan hospitals, with their staffs of renowned teachers, ensures, the Scottish medical schools seem fully to retain their popularity, not only, as is natural, among Scotsmen and their colonial descendants, but among medical students from England, Wales, and Ireland, and, indeed, all parts of our Empire. And undoubtedly the competition of other centres has had the advantage of making Scottish teachers bestir themselves, with the result that the efficiency of the medical schools is now much greater than a decade ago. The advantages derived from the second half of the Carnegie Bequest, *i.e.*, the improved equipment of the teaching schools and the encouragement of post-graduate research are proving potent factors in promoting the well-being of the Universities and Scottish education generally. Of the four universities, Edinburgh, of course, occupies the premier position as a medical school, but at Glasgow, Aberdeen, and St. Andrews, an almost equally good—indeed, in individual details, better—training can be obtained. Two ordinary qualifications to practise are granted in Scotland—the M.B., Ch.B. of the Universities, and the triple qualification of the Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow. The examinations for the University degree naturally are more exacting than those for the triple qualification, and the curriculum wider. Nevertheless, the standard for the latter is much higher than formerly, though on account of the large number of examiners in most subjects it is probably slightly less uniform than that of the universities, where the examinations are conducted by the professors with one or more extra-mural assessors in each subject. Two features of the Scottish system deserve mention—first, as regards the co-ordination of various separate teaching bodies in each centre ; second, as regards the conditions under which the students live. Around each university there has grown up an extra-mural medical school, in which the teachers are hospital physicians, surgeons, and specialists unconnected with the university, but whose classes qualify for graduation. Thus the student has usually ample choice, and can, within certain limits, attend the teacher from whom he thinks he will derive most benefit, while the extra-mural lecturers, being unendowed and constantly recruited by fresh blood, have a permanent incentive to keep their courses up to the mark, since any slackness is at once followed by a diminution in the number of students' fees. In late years instead of each extra-mural teacher lecturing separately, combinations have been formed, in which different parts of a course on medicine are given by different physicians, and these have proved exceedingly popular and successful. A very important part of the student's clinical work, too, is done at institutions and under teachers quite unconnected with the universities ; this is his dispensary practice, which may be taken at one of several dispensaries situated in the poorer districts of the towns. Until recently, practical training in obstetrics was one of the least satisfactory parts of the teaching in Edinburgh, and many students were in the habit of going to Glasgow or Dublin for their maternity work. Recently, however, steps have been taken which should render this unnecessary, and ought to give Edinburgh students quite sufficient opportunity of acquiring as good a practical acquaintance with this most important subject as they have of obtaining a theoretical knowledge of it. From what has been said it will be seen that university undergraduates and triple qualification men rub shoulders at every turn—in the wards, dispensary, and lecture-room. University students have the privilege of studying under both intra- and extra-mural teachers, while men going up for the triple qualification are limited to the latter. It is not uncommon, therefore, for a man to come up intending to take the licence, and to change his mind and go in for a degree, or *vice versâ*; and this can usually be done without much added expense or taking out many fresh classes, provided the change is not made too late in the curriculum. The weak spot in the Edinburgh curriculum is the overcrowding of subjects in certain years, but the new three-term session, with the increased frequency of professional examinations, which comes into operation on October, 1907, will do much to remedy this, and make the course more elastic.

For the rest, the student lives as he likes and where he likes; the authorities only demand that he shall attend classes with due regularity and diligence, and exhibit sufficient proficiency to pass his examinations. Most men live in lodgings, a few board with private families, and some live in the various halls of residence which have been established. In these last, too, the student is his own master, the halls being managed solely by a committee of the residents for the time being. It is impossible to make any very definite statement as to the relative cost of a medical education in the different schools, as compared with London and Dublin, as so much depends on the extra classes taken out, the mode of living, and so on. The minimum inclusive fees for the licence are £120, for the M.B. degree about £146; but almost every student finds it practically necessary to attend additional classes. On the whole, the cost of living is highest in Edinburgh, lowest in Aberdeen; in the former, while the rent of lodgings is lower than in London, maintenance, including clothing and provisions, is somewhat more expensive. Incidental expenses, amusements, &c., are, however, considerably less in the Northern capital. In Aberdeen, money goes much further than in the south, and the student ought to keep himself on about two-thirds of the funds required in Edinburgh.

THE CARNEGIE TRUST.

Through the munificence of Mr. Andrew Carnegie, LL.D., payment is now made "of the whole or part of the ordinary class fees exigible by the Universities from students of Scottish birth or extraction, and of sixteen years of age or upwards, or scholars who have given two years' attendance, after the age of fourteen years, at State-aided schools in Scotland, or at such other schools and institutions in Scotland as are under the inspection of the Scottish Education Department."

The Trust provides for the payment of the class fees of the above students proceeding to graduation in medicine or science. Application for payment of class fees under the conditions of the Trust should be made to the Secretary, Mr. W. S. McCormick, Merchants' Hall, Hanover Street, Edinburgh.

UNIVERSITY OF EDINBURGH.

Four degrees in medicine are granted: Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in medical and surgical study for five years, after passing a preliminary examination in general knowledge in accordance with the medical ordinances. A degree in Arts or Science of a British or other recognised University is held to supersede such preliminary examination. The subjects included in this general examination are English grammar and composition, English history and geography, Latin, arithmetic, and the elements of mathematics, and Greek, or French, or German.

The *annus medicus* of each year is constituted by at least two courses of not less than one hundred lectures each, or by one of such courses, and two courses of not less than fifty lectures each, exclusive of the clinical courses. Two years of the five must be spent at the University, the remaining three years at any other Medical School recognised by the University Court.

During the first four years the student must attend botany, zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence during courses of not less than 2½ months each; public health, not less than forty lectures; practical anatomy, during two courses of not less than five months each; chemistry, anatomy, physiology, pathology, surgery, materia medica, medicine and midwifery during courses of not less than five months each. He must attend a course of twenty-five lectures on practical pharmacy, or have dispensed drugs for a period of three months in a recognised hospital or dispensary. He must attend a nine months' course in clinical medicine and in clinical surgery. During the fifth or final year he must be engaged in clinical study for at least nine months. In all, before graduation, he must have done hospital work for at least three years, and have acted as clerk in the medical and surgical wards and attended for six months the practice of a dispensary, or of a physician and surgeon. He must also have studied (1) operative surgery; (2) mental diseases; (3) *post-mortems*, fevers, and diseases of the eye, and (4) one of the following. Diseases of children, of the ear, nose and throat, or of the skin; (5) vaccination.

He must attend at least twelve cases of labour under the superintendence of a registered medical practitioner or six such cases, and, for at least three months, the practice of a midwifery hospital.

Each candidate is examined both in writing and *vivâ voce* —

1. On zoology, botany, physics and chemistry.
2. On anatomy and physiology.
3. On pathology, and materia medica and therapeutics.
4. On medicine, surgery, midwifery, forensic medicine, and public health.

On October 1st, 1907, a new division of the medical curriculum will be inaugurated, the year being divided into three sessions, a 1st winter, a 2nd winter, and a summer session. At the end of each of these professional examinations will be held, instead of twice yearly as at present. This will admit of some re-arrangement of classes, pathology being taken before materia medica, instead of concurrently or subsequently, as at present.

The new order of examination will be as follows:— Physics, end of first half of first winter session; Chemistry, end of second half of first winter session; Zoology and botany, end of first summer session; Physiology, end of second summer session; Anatomy, end of first half of third winter session; Practical materia medica, end of second half of third winter session; Pathology, end of third summer session; Materia medica, end of second half of fourth winter session; Medical jurisprudence and public health, end of fourth summer session; Midwifery, end of first half of second winter session; Medicine and surgery, end of second half of second winter session; Clinical medicine, surgery and gynæcology, end of fifth summer session.

The degree of Doctor of Medicine may be conferred on any Bachelor of Medicine and Bachelor of Surgery, and who is of the age of twenty-four years, and who produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and Ch.B., for at least one year in attendance on a hospital, or in scientific work bearing directly on his profession, or in the military or naval medical services, or for two years in practice other than purely surgical. The candidate shall submit to the Faculty of Medicine a thesis on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor in Surgery. The candidate will also be examined in clinical medicine and must show practical acquaintance with advanced methods of diagnosis; he *may* take, at option, gynæcology, mental diseases, or diseases of children for one of his three cases. The degree of M.D. is conferred on holders of the degrees of M.B., C M. (Old Regulations) on the submission of a thesis approved by the Medical Faculty, provided that the candidate shall have passed the preliminary examination in the subjects of Greek and logic or moral philosophy. Should the candidate elect to do so, he may, however, take the M.D. degree under the new regulations, *i.e.*, substituting an examination in clinical medicine for that in Greek and logic. This course is usually pursued by those who did not pass in these subjects with the rest of their preliminary examinations.

The regulations for the degree of Ch.M. are very similar.

Fees :—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas (Old Regulations, £5 5s.).

The total expense of the curriculum, including examination and matriculation fee, is £146.

Among scholarships, &c., open for competition during the session 1907-8 are the following :—Vans Dunlop scholarship, value £100, in chemistry, anatomy and physics, in botany and zoology, and in physiology and surgery. Stark scholarship in clinical medicine, value £110 ; Buchanan scholarship in midwifery, value £40 ; Mouat scholarship in practice of physic, £57. Mackay Smith scholarship in chemistry, value £25. A Creighton research scholarship (anatomy and physiology) £100. Houldsworth scholarship, re-search in pharmacology,£49; McCunn medical research scholarship, £100. There are also a great many other bursaries Fellowships, and prizes open during the session 1907-8, and for the details governing entry for these the University Calendar (James Thinn, South Bridge, Edinburgh) should be referred to.

Graduation in Public Health: Degrees (B.Sc. & D.Sc.) are also conferred in Public Health. Candidates must be graduates in medicine and must matriculate for the year in which they proceed for examination. They must (1) have worked at least twenty hours a week during a period of not less than eight months in a recognised Public Health laboratory—five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh; and (2) have attended a course of lectures on physics in addition to that qualifying for graduation in medicine, and one on geology.

Candidates for the second examination are not admitted until at least eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two courses of Public Health, one dealing with medicine, the other with engineering, in relation to public health. They must also have studied practical sanitary work under a Medical Officer of Health for six months, have had three months' clinical instruction in a fever hospital, and three months' instruction in mensuration and drawing.

Fees for Science Degrees : B.Sc., first examination, £3 3s. ; B.Sc., second examination, £3 3s.

Diploma of Tropical Medicine.—Every year an increasing number of candidates avail themselves of the University Diploma of Tropical Medicine and Hygiene, which is conferred only on those possessing a degree in medicine. The course includes practical bacteriology, diseases of tropical climates, tropical hygiene, the zoological character and life history of disease-carrying insects and venomous animals, clinical instruction at an hospital for tropical diseases. The examination is held in January and July, the fee being £4 4s.

University Hall, Edinburgh.—In an educational number it is worth while to call attention to the advantages now offered to students coming to Edinburgh to study, in the shape of social residences, in which students can live in a self-governing community. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges vary from 7s. 6d. to 22s. 6d. per week. The residents elect a treasurer from among their number who acts as intermediary between them and the housekeeper or servants. It is a satisfactory indication of the comfort of the Hall that many graduates live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents, or other suitable person. These are considered and voted on at a house meeting. The Hall is an admirable place for parents to send their sons to. Any unruly member may be expelled by a meeting of the residents similar to that held for elective purposes.

Medical School for Women.—The medical teaching of women in Edinburgh is carried on by the Scottish Association for the Medical Education of Women (the Secretary, Minto House, Chambers Street). The classes are conducted by the lecturers of the Medical School of the Royal Colleges, and qualify both for the Edinburgh University degree and for the Licence of the Triple Board. The classes are for women alone. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes without special cause shown. Women students are eligible for the benefits of the Carnegie Bequest.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but eight of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations, laid down in Ordinance No 14, Glasgow No. 1, of the Commissioners under the Universities (Scotland) Act, 1889, four degrees, open both to men and to women, are conferred—M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Elementary mathematics, and (4) Greek, French, or German, with possible option to students whose native tongue is not English in the case of the fourth subject, and, on passing, students must register in the books of the General Medical Council. By a regulation recently enacted, it is no longer compulsory to pass in all the four preliminary subjects at once, and they may now be passed at two stages. For M.B. and Ch.B. a curriculum of five years is required. A syllabus with full details of the curriculum and of the preliminary examination may be had, post free, on application to the assistant clerk, Matriculation Office.

The fees for M.B. and Ch.B. are £23 2s. ; for M.D. £10 10s., and for Ch.M. £10 10s. For hospital attendance there is an initial fee of £10 10s., with a further fee of £3 3s., for each winter session, and £2 2s. for each summer session of clinical instruction. There are three very extensive general hospitals in the city, which afford exceptional opportunities for clinical work, while the Royal and other asylums, the City Fever Hospitals, the Maternity Hospital, the Sick Children's Hospital, the Eye Infirmary, &c., give facilities for the study of special branches.

The degrees of B.Sc. and D.Sc. in Public Health and of B.Sc. in Pharmacy, are also now conferred. Of late the University has made considerable efforts to extend its laboratory accommodation and equipment, to augment its teaching staff, and to encourage post-graduate and research work. Within the last few years there have been provided new laboratories in the departments of pathology, anatomy (costing £13,000), chemistry, and surgery (costing £9,900); while new laboratories, to cost, with equipment, upwards of £60,000, are now approaching completion, for the departments of physiology, materia medica, and medical jurisprudence and public health.

Bursaries and prizes to the annual amount of about £1,000 are appropriated to medical students, including an Arthur bursary for women, £20 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and Scholarships and Fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course.

Queen Margaret College for Women. — Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing University instruction, or its equivalent, within the reach of women), Queen Margaret College in 1890 added to its faculty of Arts a School of Medicine for Women. This was organised entirely on University lines, and with the view of preparing for University degrees; and when, in 1892, in consequence of the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B. and Ch.B. is given by University professors and lecturers, with excellent facilities for hospital and dispensary work in the Royal Infirmary and other hospitals. A Hall of Residence for the students was founded in 1894. Fees for the classes at Queen Margaret College may be paid by the Carnegie Trustees; and several bursaries are open to women students of medicine,

The Winter Session begins on 17th October. The prospectus can be obtained from the hon. sec., Miss Galloway, Queen Margaret's College, Glasgow.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, Agriculture, and in Education. It is, moreover, a teaching body equipped with twelve distinct chairs in the various branches of medicine and surgery. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of study is nearly the same as in the University of Edinburgh; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, each candidate for the degrees of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Total cost, exclusive of the fees for degrees, is about £120. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions.

Bursaries.—Bursaries, Scholarships, and Fellowships to the number of fifty, and of the annual value of over £1,180, may be held by students of medicine. (See "University Calendar.")

The Degree of M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of M.B. and C.M. (Old Regulations), is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years in attendance in a hospital, or in military or naval medical service, or in medical or surgical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates for the degree of M.D. (New Regulations) are required to pass an examination in clinical medicine in addition to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine in any University in the United Kingdom. Regulations may be seen in the "Calendar," or obtained on application to the Secretary the Medical Faculty.

Aberdeen Royal Infirmary.—This is a well-equipped institution, containing 250 beds, and affords excellent opportunities for clinical study to students at the Aberdeen University. The city, moreover, offers inducement in the way of cheaper living and comparative quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

ST. ANDREWS UNIVERSITY.

United College St. Andrews and University College, Dundee.

This University (session opens October 15th) grants the degrees of M.B., Ch.B., M.D., and Ch.M. The degrees of the University are open to either sex. For the degree of M.B., Ch.B., two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or in any foreign, Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The preliminary examination and the professional examinations are of the same character as in the other Scottish Universities. A Diploma in Public Health is also granted by the University of St. Andrews to graduates in medicine of any University in the United Kingdom. Twelve months must elapse between the date of graduating in medicine and entering for the examinations for the diploma. The course of study required consists of (1) a six months' course of practical chemistry, bacteriology, and the pathology of diseases transmissible from animals to man in a laboratory of the University of St. Andrews; (2) six months' work with a medical officer of health; (3) three months' clinical instruction in infectious diseases. Subjects for first examination:—Chemistry, physics, bacteriology, and meteorology. Second examination:—Sanitation, sanitary law, vital statistics, medicine in relation to public health.

University College, Dundee, was affiliated and made to form part of the University of St. Andrews on January 15th, 1897, and the whole medical curriculum may be taken in the College. The United College, St. Andrews, offers classes for the first two years of professional study.

Bursaries and Scholarships.

United College, St. Andrews. — Malcolm bursary, £25 a year, tenable for five years. Fourteen Taylour Thomson bursaries, £30 to £20, five tenable for one year, nine for two, open to women only proceeding to graduate in medicine.

University College, Dundee: — Eleven entrance bursaries of £15, open to women for arts, science, or medicine, tenable for one year. Four £20 and three £15 second year bursaries for men or women in arts, science, or medicine, tenable for one year. Four £20 and two £15 third year bursaries for men or women in arts, science, or medicine, tenable for one year. Two Educational Trust bursaries of £25, tenable for three years. Applicants must have attended a public or State-aided school in Dundee for at least one year before examination. Bute bursary, annual income from £1,000 (men only).

Preliminary Examinations.—The dates of the next two examinations are September 27th, 1907, and March 27th, 1908. Schedules (obtainable from the Secretary of the University) to be returned filled up, and fees paid by September 14th, 1907, or March 11th, 1908.

Fees for Degrees.—Total fees for M.B., Ch.B., are the same as at other Scottish Universities, *i.e.*, 22 guineas (payable in instalments). Fee for the degree of M.D., and also for that of Ch.M., is 10 guineas in each case. For the Diploma of Public Health examinations the fee is £5 5s. for each of the two examinations.

Class Fees.—The fee payable in each of the following classes is 4 guineas, *viz.*:—Chemistry, physics, zoology, botany, physiology, anatomy, materia medica, pathology, forensic medicine, and public health, medicine, surgery, and midwifery. The fee for the practical classes in these subjects is 3 guineas each. In clinical surgery, clinical medicine, ophthalmology, diseases of the throat, nose, and ear and mental diseases, the class fees are 2 guineas each. The fee for Public Health chemistry required for the D.P.H., is 7 guineas. A special class in Bacteriology is also held for the D.P.H. for which the fee is 3 guineas.

Dundee District Asylum.—The appointments include a qualified resident assistant and two resident clinical clerks. Clinical instruction is given.

Further information will be found in the Calendar of the university published by Messrs. Blackwood and Sons, Edinburgh, or can be had of the Dean of the Medical Faculty, Professor C. R. Marshall. (See advertisement page).

Dundee Royal Infirmary.—The Infirmary contains 360 beds, with a special ward for the treatment of children. Three resident qualified assistants are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. Out-patients are seen daily at 9 a.m. The instruction given at the Infirmary is recognised for purposes of graduation by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital Ticket for the Infirmary, £2 2s. each session, or £3 3s. a year. Further information on application to the Medical Superintendent.

THE COLLEGES.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after a series of examinations, the student may obtain the diploma of the co-operating bodies, and can register three diplomas under the Medical Acts, *viz.*, Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow.

The three bodies grant their *single* qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery as the case may be.

Regulations of the Conjoint Board of the Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons, Glasgow.—The candidate must produce certificates of having attended the following course of lectures, the certificate distinguishing the sessions and the schools in which the courses were attended. Anatomy, six months; practical anatomy, twelve months; chemistry, six months; practical chemistry, three months; materia medica, three months; physiology, six months; medicine, six months; clinical medicine, nine months; surgery, six months; clinical surgery, nine months; midwifery, three months; medical jurisprudence, three months; pathology, three months. The candidates must also produce the following certificates:—(*a*) Of having attended six cases of labour under the superintendence of a registered practitioner. (*b*) Of having attended for three months' instruction in practical pharmacy. The teacher must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of a laboratory of a public hospital or dispensary, or a registered practitioner, or a teacher to a class of practical pharmacy. (*c*) Of having attended for twenty-four months the medical and surgical practice of a hospital, containing eighty patients, and possessing distinct staffs of physicians and surgeons. (*d*) Of having attended for six months the practice of a public dispensary, or of having assisted for six months a registered practitioner. (*e*) Of having been instructed in vaccination.

First Examination, Fee £5.—The first examination shall embrace chemistry, physics, and elementary biology, and shall take place not sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must produce certificates of attendance on chemistry, practical, chemistry, anatomy, and six months' practical anatomy.

Second Examination, Fee £5.—The Second examination embraces anatomy and physiology and shall not take place before the termination of the summer session of the second year of study. Candidates must produce certificates of attendance on anatomy, practical anatomy, and physiology.

Third Examination, Fee £5.—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

Final Examination, Fee £15.—The Final examination embraces medicine (including therapeutics and medical anatomy, clinical medicine); surgery (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynæcology, medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education: (1) English grammar and composition; (2) Latin, grammar, translation from specific authors and easy unseen translation; (3) (*a*) arithmetic, to vulgar and decimal fractions; (*b*) algebra, to simple equations; (*c*) geometry, to the first two books of Euclid; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (5) one of the following:—(*a*) Greek; (*b*) French; (*c*) German; (*d*) Italian; (*e*) any other modern language; (*f*) logic; (*g*) botany; (*h*) zoology; (*i*) elementary chemistry.

Qualification in Public Health: The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson, 48, George Square, Edinburgh; and for those of the Royal College of Physicians, to Dr. H. Rainy, 16, Great Stuart Street, Edinburgh.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a member of the college for at least three years, and have attained the age of twenty-seven years.

The Membership is conferred only on a licentiate of a college of physicians or graduate in medicine of a British or Irish University, provided he shall have attained the age of twenty-four years and shall have passed an examination on: (1) medicine, including therapeutics (2) on one of the following optional subjects, *in which a high standard of proficiency is expected* —(*a*) a department of medicine specially professed; (*b*) psychological medicine; (*c*) pathology; (*d*) medical jurisprudence; (*e*) public health; (*f*) midwifery; (*g*) gynæcology. The examination is of a searching character extending over three days, the first of which is devoted to clinical and side room work, and written commentary on a case examined. The second day is taken up by written papers, and the third by practical examination on special subject and orals.

The fee for membership is 35 guineas, for fellowship 38 guineas, with a stamp duty of £25—£101 13s. in all.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations for this licence are held on the first Wednesday of each month, save those of September and October, in medicine, materia medica, midwifery, and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing) only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates, and which are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (*a*) Surgery, special branches; (*b*) advanced anatomy and physiology; (*c*) surgical pathology and morbid anatomy; (*d*) midwifery and gynæcological medicine and surgery; (*e*) medical jurisprudence and hygiene; (*f*) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship of either college.

LICENCE.—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee, £15 15s.

DENTAL DIPLOMA.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 10s.

Edinburgh Royal Infirmary.—Clinical instruction is afforded at this institution, which contains 800 beds under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, physical diagnosis, diseases of the skin, eye, ear, throat and teeth, and anæsthetics. Separate wards are devoted to venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate tickets amounting to £12 12s. entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

The appointments are as follow:—

1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months.
2. Non-resident physicians and surgeons (in the special subjects and for out-patient work) are appointed for six months. These appointments may be renewed.
3. Clerks and dressers are appointed by the surgeons and physicians. These are open to all students and junior physicians holding hospital tickets.
4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

ROYAL HOSPITAL FOR SICK CHILDREN.—During the year three courses of clinical instruction are given by the staff of the hospital, who are recognised as University Lecturers on the subject. The course consists of clinical lectures, ward cliniques, attendance at *post mortem* and out-patient cliniques. Hospital tickets, £1 1s.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1505, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled "The School of Medicine of the Royal Colleges, Edinburgh." The present number of lecturers is about sixty, of whom the greater number deliver qualifying courses of instruction of the same duration and scope as those delivered within the University, while a large number of non-qualifying courses on special subjects of interest to medical science, but which are not required for graduation, are delivered both in the winter and summer sessions. The students who attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other qualifications, such as the triple qualification of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow; that of the Royal College of Physicians of London, and the Royal College of Surgeons of England, and the degrees of the different Universities. The number of students attending the school averages 1,300 annually.

The minimum cost of the education in the School of Medicine for the triple qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £120, which is payable by yearly instalments during the period of study.

The Winter Session opens October 2nd.

GLASGOW EXTRA-MURAL SCHOOL.

St. Mungo's College and Glasgow Royal Infirmary.—This college was incorporated in 1889 under its new title, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purpose of the medical school in the grounds of the hospital, and the laboratories, museums, and lecture rooms are of the most approved description. The college has been recently equipped with a complete electric light installation, and a powerful electric educational lantern. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has over 600 beds available for clinical instruction, including an ophthalmic department, and it has special wards for diseases peculiar to women, for venereal diseases, burns, and diseases of the throat, nose, and ear. At the dispensary special advice and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

Appointments.—All appointments are open. There are five physicians' and eight surgeons' assistants, who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and surgery. Clerks and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are valuable to students. In the pathological department assistants are also appointed by the pathologist.

Fees.—The fees for Lectures, including hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, amount to about £70.

Anderson's College Medical School, Glasgow.—New and excellently equipped buildings were opened in October, 1887, in Dumbarton Road, immediately to the west of the entrance to the Western Infirmary, and within four minutes' walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery and public health. There are also provided a library, reading room, and students' recreation room. The buildings are constructed upon the most approved modern principles. The dissecting room is open in winter from 9 a.m. to 6 p.m., and in summer from 6 a.m. to 6 p.m. These students are assisted in their dissections by the professor and demonstrators, by whom daily examinations and demonstrations on the parts dissected are conducted. The supply of subjects is ample, and students are consequently provided with parts as soon as they may be ready for them. The dissecting room is provided with a complete series of dissecting specimens mounted in plaster of Paris illustrating the anatomy of the human body. There is also a large Bone Room, furnished with complete sets of painted and unpainted bones.

The various courses of instruction qualify for all the Licensing Boards in the United Kingdom, and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow, under certain conditions. The courses in public health (laboratory and lectures) are also recognised by the University of Cambridge.

The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from W. S. McCormick, Esq., LL.D., Carnegie Trust Offices, Edinburgh.

Class Fees.—For each course of lectures (anatomy, ophthalmic medicine and surgery, aural surgery, diseases of throat and nose, and mental diseases excepted), first session, £2 2s.; second session (in Anderson's College), £1 1s.: afterwards free. For the following practical classes, *viz.*: Chemistry, botany, zoology, physiology, pharmacy, first session, £2 2s.; second session, £2 2s.; in botany and zoology, practical and systematic course together, £3 3s. Operative surgery, £2 12s. 6d.; second course, £2 2s. Joint fee for classes of systematic and operative surgery, £3 13s. 6d. Public health laboratory, £11 11s.; with lecture £12 12s. Ophthalmic, medicine and surgery, aural surgery, diseases of throat and nose, mental diseases—each, £1 1s.

Anatomy Class Fees.—Winter: First session (including practical anatomy), £4 4s.; second session (including practical anatomy), £4 4s.; third session, £2 2s. To those who have had the necessary courses of practical anatomy, the fee will be £1 1s. Summer: Lectures and practical anatomy, £2 12s. 6d; separately, £1 11s. 6d. each.

Royal Infirmary.—Fees: Hospital practice and clinical instruction, first year, £10 10s.; second year, £10 10s.; afterwards free. Six months, £6 6s.; three months, £4 4s.; pathology, both courses, £4 4s.; vaccination fee, £1 1s.

Dental Curriculum.—Students studying with a view to the dental diploma can obtain instruction in the following subjects: Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, 15, Dalhousie Street, Glasgow. Particulars may be had from D. M. Alexander, Esq., 97, West Regent Street.

The International Congress on the Protection of Infant Life will open in Brussels on September 12th, and will go on till the beginning of next week. It is the second international congress on the subject, the first having been held in Paris two years ago. It was instituted for the prevention of infant mortality, and the work of the congress falls under three headings, namely, those dealing with: (1) Giving advice to mothers; (2) Encouraging breast-feeding; and (3) The distribution of milk to those infants for whom breast-feeding is either impossible or insufficient. The Organising Committee of the Brussels Congress, however, consider the extension of this programme is necessary, and it is proposed to consider the question of widening the scope of the Congress so as to include all questions relating to the welfare of infants. The matter will be brought before the Congress this week, and there is little doubt that it will meet with a hearty welcome from the delegates.

There is a serious outbreak of small-pox in Vienna, and on Saturday 24,632 persons were vaccinated by public officials, making 106,000 in the last few days. The police have forbidden public meetings and processions.

FRANCE.

Paris, Sept. 8th, 1907.

Obesity.

Obesity develops frequently after an acute infection, or in the course of a chronic infection. Such cases have been observed so constantly that Bouchard affirmed in his statistics that in one-fifth of the cases an acute affection might be found at the origin of obesity.

Experimentally, a notable increase in weight can be provoked by a toxic infection. It is thus that Professor Carnot obtained, in more than one instance, a considerable development by injecting cultures of the bacilli of Eberth into rabbits; their weight more than doubled.

Clinically, an embonpoint consecutive to an infection has been remarked long since, and one of the most frequently noted in this respect is typhoid fever; post-typhoid obesity is frequently observed during the convalescence; a remarkable reaction takes place in the tissues, glands, and the different systems; the appetite is, on the other hand, almost insatiable.

Obesity is observed also in the course of chronic suppurations and recently M. Carnot had seen a case where the obesity followed chronic renal suppuration.

Even in the course of cancer, where cachexia is the rule, the mesentery and the epiploon have been frequently found loaded with fat.

Among the cases of obesity due to infectious maladies, tuberculous and syphilitic obesity take the first rank.

The relations between obesity and tuberculosis are more frequent than is generally believed; stout tuberculous patients are not very rare.

It is thus that Laennec speaks of cases of tuberculosis where the patients maintained their embonpoint; and Milcent says that frequently a considerable local lesion coincides with an otherwise healthy condition, and even with embonpoint.

Ferrand and Quinquand remarked the facility with which certain scrofulous patients increased in weight under treatment.

Sarda and Vires speak of tuberculous patients in whom nothing reveals the pulmonary lesions with which they are affected. "It is certainly not on their face that the diagnosis can be read; they are generally more or less developed and some really stout."

Lemoine, in his lectures on fat phthisical patients, insisted on certain cases of torpid tuberculosis presenting externally all the appearance of health and even of embonpoint, and showed how such an aspect could lead to an error in prognosis.

These forms were, he said, frequently curable, the patients belonging more or less to the chlorotic type.

Daremberg, on the contrary, says that the embonpoint is deceptive; such patients prolong their life, it is true, but hardly ever get well; they are incapable of consuming an excess of food which poisons them if overfed.

M. Carnot has seen several cases of obesity provoked by the infection a few months after an attack of hæmoptysis; frequently, also, under the influence of overfeeding and rest, tuberculous patients have been known to increase more rapidly in weight than normal subjects.

It would similarly seem that in many agricultural shows, the fattest animals have been discovered to be affected with tuberculous ganglions.

Syphilitic obesity sometimes appears at the outset of the infection, and in a certain number of cases overfeeding has had some influence in predisposed subjects, but in the majority of cases the automatic regulation of nutrition does not act normally on account of the insufficient functions of the different glands of secretion genital glands, thyroid body, &c.)

Thus considered, and no matter how their intimate mechanism acts, obesity on the one hand, emaciation on the other, should be considered as morbid syndroma, indicating a trouble in nutrition, derived frequently from the same causes.

GERMANY.

Berlin, Sept. 8th, 1907.

At the Otological Society, Hr. Sonntag showed

Two Cases of Otitic Pyæmia.

A man, æt. 36, who had suffered from pain in the ear for a fortnight and a rigor twenty-four hours before. There were granulations and a fistula in the upper and posterior part of the wall of the auditory meatus. Temperature 41 C. The opened-up sinus looked velvety and pulsated. A fortnight later a secondary plastic operation was performed. Contrary to Voss, of Riga, he did not look upon puncture of the sinus as free from danger. He had seen the punctured spot become purulent. (*b*) A man, æt. 24, who had had suppuration of the left ear for a fortnight and two days ago a rigor with mental dulness and a yellow tinge of the skin. The meatus was swollen. No nystagmus. The part was completely chiselled out. Cholesteatoma. Fistula of the horizontal semi-circular canal. The sinus, when opened up, appeared to be collapsed. Opening of the sinus, which contained a little fluid. The sinus was bordered on both sides by solid thrombus. The temperature from that time remained normal, and a month later a plastic operation was performed.

Neuronal.

(*c*) Dr. George Dreyfuss, of the University Irrenanstalt, Heidelberg, reports his experiences with neuronal in the Therap. Monatsh. May, 1906. The drug was given to seventeen patients in 1905, sometimes as a calmative, when there was great excitement, and sometimes as a hypnotic, when all other means of overcoming the sleeplessness failed. The sleep produced lasted variously, according to the degree of excitement or agrypnia. Calm and only sleepless patients generally went to sleep in a quarter to half an hour after taking the medicine. The sleep was deep and mostly uninterrupted. Excited patients took a longer time, one to three hours or even longer before sleeping, but they frequently quieted down in an hour. The doses, according to the object aimed at, varied in amount; 0.5 gm. sufficed in simple cases of sleeplessness, but 1 gm. was required in obstinate cases. In cases of excitement, especially those of a catatonic kind, larger doses had always to be given; 1.5 gm. as a minimum, 2 gm. as an average, and sometimes as much as 2.5 gm. These doses were never exceeded in the twenty-four hours. There were disagreeable effects in two cases. In one, violent headache came on the second day; in another, an arterio-sclerotic patient, who had been given 2 gm. of the medicine, it had to be stopped as it caused headache, mental disturbance and a very marked rapid and dicrotic pulse. It did not appear to have any cumulative properties, nor was it observed to lose its effect. In many patients high doses were given for three or four weeks together, and the like effect was produced, whether given in the form of powder or tablet. In certain control experiments veronal alone appeared in general to be superior to neuronal. Chloral was not so certain, whilst trional was less powerful and the like effect was only obtained by larger doses (neuronal, 1 to 1.5 gm.; trional, 2 gm.). Paraldehyde failed completely even in large doses, in one case in which neuronal was quite successful.

AUSTRIA.

Vienna, Sept. 8th, 1907.

Pleiochromic Icterus.

Soucek in a long article on the origin of urobilin relates several cases of pleiochromic icterus, which he recognises as a transformation of the bilirubin into urobilin. This is an old controversy. Whence comes the urobilin? In this case Soucek is in favour of the transformation theory from biliverdin and bilirubin, and it may or may not be a normal constituent of the urine. Urobilin has the chemical formula of hæmatoidin, but differs in spectroscopical analysis. Others have it that urobilin is only a hydroxid of bilirubin and can be obtained from the latter by deoxidation, according to Jaffe's experiments. MacMun, on the other hand, affirms that there is no identity existing between urobilin and hydrobilirubin, and further assures us that there are two urobilins to be found in the urine, while some authors aver that frequently no urobilin can be found in perfectly healthy urine. Here we have a wide divergence of opinion all based on experiments. MacMun has a febrile urobilin and a normal urobilin, both bodies having a similar chemical composition, but differing in their spectroscopical analysis; in normal urobilin the absorption line disappears, while in the febrile does it not. The æther solution of the febrile has two faint lines near D, while the normal has nothing. From this he reasons that the product is an aqueous peroxide of a sulphuric alcoholic hæmatin solution, which is identical with normal urobilin. Other experiments have got yellow, red and brown lines on both sides of D, which weaken the last theory. Stokvis affirms that the urobilin is obtained from the bilirubin. Hoppe-Seyler has it from the hæmaglobin and hæmatin, while Nobel believes it is a form of hæmatoporphyrin

Whatever the body may be Soucek found an entire absence of bilirubin throughout a febrile illness, while the urobilin reaction was constantly present. The blood was analysed at the same time and found to contain bilirubin. This, he thinks, settles the question that urobilin is nothing more than a transformation of bilirubin which takes place in the kidneys.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

Public Health.—The report of the Medical Officer of Health at the last monthly meeting of the Corporation showed the lowest death-rate that has been known in the city for many years, 15.4. That from zymotic diseases was 1.0, and from chest affections, 5.2. During the preceding four weeks the cases of cerebro-spinal meningitis which had been notified, numbered 13, so that a steady decline in the epidemic goes on. Erysipelas, which had been rather prevalent lately, was also declining One case of anthrax occurred. There are now only seven cases of cerebro-spinal meningitis under treatment at the Purdysburn Fever Hospital. It appears that the public has got over its dread of the disease, which was at first fostered by the alarmist paragraphs in the daily Press, and as case to case infection is, to say the least, not very obvious, cases are now kept at home instead of being sent to hospital.

Queen's College: President's Annual Report.—President Hamilton's annual report, just issued, shows the College to be in a most flourishing and satisfactory state. The number of students is high in all faculties, and the facilities for study, thanks to the Better Equipment Fund, are greater than they ever were. Seven assistants have been appointed in various departments, including Dr. Howard Stevenson, as assistant to the professor of surgery, and Dr. C. G. Lowry to the professor of midwifery. Six of the seven new appointments are filled by old students of the College, and the President points out that these appointments confer a double benefit, helping brilliant young graduates of the school, and encouraging research and higher education. Twenty years ago the entire teaching staff of the College numbered just twenty, and now that number is doubled. The new laboratories, which are to be opened by Lord Kelvin at the end of this month, will also add to the teaching facilities of the College. These have been provided out of a Treasury grant of £5,400, with an equal sum contributed by the Better Equipment Fund, and bring the number of laboratories in the College up to eight, all well fitted and convenient for work. A new scholarship, established by the munificence of Mr. Robert Mackay Wilson, Fitzwilliam Square, Dublin, will be much appreciated by medical students, as it takes the form of a travelling medical scholarship of the value of £100 per annum.

LETTERS TO THE EDITOR.

THE MEDICAL ASPECT OF DENTAL CARIES IN CHILDHOOD.

To the Editor of The Medical Press and Circular.

Sir,—I imagine that most physicians have long been familiar with the fact mentioned by your correspondent in The Medical Press and Circular of August 28th, that enamel when its development is complete is incapable of physiological activity. He makes an assertion, however, which I venture to question, when he says that the temporary teeth "can be influenced only through the mother." As a matter of clinical experience I make bold to say that there is no proof that this is so, on the contrary, there is much to suggest that the development of the enamel of the temporary teeth can be influenced very distinctly by disease after birth; and if it were necessary to quote a dental authority to show that this is possible, I would refer your correspondent to Tomes, who says in his "System of Dental Surgery," 4th edition, p. 98, "The calcification of the temporary teeth is not so far advanced at the time of birth but that we might expect them to be influenced by the occurrence of disturbing causes during the first month or two after birth"; and on p. 3, "The temporary teeth in a nine months' fœtus are partly formed. The central incisors are calcified through most of the length of the crown, but the lateral teeth are less advanced. The terminal points only of the canines are calcified while the masticating surfaces of the first temporary molars are completed except the enamel, which at this stage has not attained to more than half its thickness, a condition which is common also to the more anterior teeth."

Your correspondent seems even to doubt this possibility of influencing the development of the enamel of the permanent teeth after birth. It hardly seems necessary to quote dental authorities to show that for some years after birth the development of the enamel of the permanent teeth remains uncompleted, and is, therefore, capable of being influenced by disease and safeguarded by treatment which arrests the disease. It must be remembered that the mere fact that there is an outer surface of enamel does not show that the development of enamel is complete; the point which I wish to insist upon is that the thickness of enamel, upon which largely depends its effectiveness as a barrier to decay, can be influenced by nutritional disease in infancy and, although I did not say so in the remarks to which your correspondent refers, I think it is quite possible and likely that this applies in some degree to the temporary as well as to the permanent teeth. In conclusion let me say that none can be more conscious than I am that an adequate knowledge of dental pathology can only be obtained by special study and special experience such as a physician can hardly hope to attain; and if it seems presumptuous in a physician to criticise the remarks of a dental expert, I do so only in the hope that clinical medicine may gain fuller knowledge from the excellent scientific investigations which so many dental surgeons are making nowadays on obscure points such as the influence of disease in early life upon the development of the teeth.

I am, Sir, yours truly,

Geo. F. Still.

114 Harley Street, W., Sept., 2nd, 1907.

THE INEBRIATES' ACT.

To the Editor of The Medical Press and Circular.

Sir,—All those who are working to combat the evils which the Inebriates' Act was designed to deal with will be glad to hear of the announcement made by Canon Horsley in the *Times* of September 2nd. The Council of the Church of England Temperance Society is asking for a departmental enquiry into the working of the Act, and the value of the various "cures" for the reclamation of alcoholics and "narcomaniacs," and the Home Secretary has promised to receive a deputation on this subject early in the autumn. A departmental enquiry could easily be made to expose the true character of the numerous bogus and fraudulent drink cures now so extensively advertised. Some of these impostures are under the patronage of parsons and soft-headed philanthropists who ought to know better. Canon Horsley could, no doubt, easily put his finger upon some of the former class. An elementary knowledge of the psychology and pathology of the inebriate which any educated man can acquire, is sufficient to guard one against acceptance of the claims which the bogus drink-cures put forth; and the educated men who support these cures can be only such as are, in spite of their general culture, ignorant of science or perhaps scorners of science and of scientific methods. Inebriety is not always due to one and the same cause. On the contrary its causation is always extremely complex, being made up of many widely varying physical, mental, and moral factors. To claim for any drug or combination of drugs the power to attack and destroy these factors, is to claim to work miracles; and when the procedures and remedies of the miracle-monger are kept secret, and worked for commercial considerations, no sensible man of the world, and least of all a medical man of the world, will have anything whatever to do with them. A discoverer of a cure for drunkenness by drugs or any other simple means would rank among the greatest benefactors of mankind, with Jenner, Pasteur, and Lister. Wealth would surely be his, and honour—a monument in every civilised land. It is not conceivable that any real man of science would for gain withhold such a boon from suffering humanity, or would hesitate to place his discovery with full disclosure of its nature in the hands of men of science who alone are competent to tests its merits. The bogus drink-cure proprietor forms in truth one class of the army of medical impostors whose methods call for investigation by a Royal Commission as advocated so persistently in the Medical Press. If the trade of these men did no more than plunder the simple and suffering it would be bad enough; but the trade is mostly pursued with cynical and callous disregard of the injury to health and the misery it inflicts upon its victims. It is impossible to believe that if the story were once publicly told and established by evidence laws would not be speedily devised to put an end to this nefarious traffic.

I am, Sir, yours truly,

Sept, 2nd, 1907. H. S.

THE ANNUAL CATHEDRAL SERVICE OF THE GUILD OF ST. LUKE.

To the Editor of The Medical Press and Circular.

Sir,—May I draw attention to the advertisement appearing in the present issue of The Medical Press and Circular respecting the Annual Festival Service of the Guild of St. Luke, to be held at St. Paul's Cathedral on October 22nd, and request that those who desire to attend will communicate with me as soon as possible. As we are expecting a large attendance from the City Companies and others, we are anxious to allot space as soon as possible.

Claude St. Aubyn-Farrer,
Registrar.

Westbourne Park Road,
London, W., Sept. 7th, 1907.

Dr. W. H. Allchin, consulting physician to Westminster Hospital, will deliver an introductory address on the present state of medical education in London at the opening of the Medical School on October 1st. On October 4th Sir Samuel Wilks will occupy the chair at the first meeting of the Guy's Hospital Physical Society, when Dr. G. A. Gibson is to read a paper, entitled "Past and Present."

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial,* and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

C. W.—The extracts you are good enough to send are not the sort of thing we care for in this journal. They may seem amusing to a certain class of reader, and we should recommend you to try our contemporary the *Winning Post.*

CLINICAL LECTURES.

The following lectures have been received, and are hereby acknowledged. They will appear in our columns week by week in the ordinary course:—

Corner, Edwd. M., B.Sc.Lond., M.B.Cantab, F.R.C.S., "Deformities of the Foot Associated with Abduction."

Heilbronner, M.D., Professor of Medicine in the University of Utrecht, on "The Early Diagnosis and Treatment of Progressive Paralysis."

Lepine, R. M., Professor of Medicine in the University of Lyons, on "Uræmic Meningitis."

Morrison, James, M.D.Lond., "Lingering Labour: its Causes and Treatment."

Nicholson, H. Oliphant, M.D., F.R.C.P., "The Prevention of Fever in the Puerperium."

Saundby, Robert, M.D., LL.D. (Hon.), F.R.C.P.Lond., "The Sphygnomanometer in Medicine."

Sinclair, Thomas, M.D., F.R.C.S., "Traumatic Epilepsy Treated by Operation."

Stephenson, Sydney, M.B., F.R.C.S., "Congenital Anomalies of the Eye."

Stoney, R. Atkinson, M.B., B.Ch., F.R.C.S., "Cancer of the Rectum" (illustrated).

Swan, R. L., F.R.C.S., "Tubercular Diseases of the Knee-Joint and the Treatment of Sinoval Cavities."

Yearsley, Macleod, F.R.C.S., "Osteosclerosis."

Optic.—We must say that in our opinion it is hardly consistent with what is due to your colleagues, to say nothing of encouraging unqualified practice, to continue to send prescriptions for spectacles to opticians who prescribe themselves. Opticians have shown themselves extremely obstinate and we believe foolish in asserting their independence in this matter, and while medical men can get but cold comfort out of the law, they can easily and safely combine, and send their patients for spectacles only to such ethically-practising spectacle-makers as they can rely on. If the shoemaker sticks to his last, he is all the more likely to make better shoes.

NOTICE TO HOSPITALS AND COLLEGE DEANS.

The Editor desires to thank those gentlemen attached to the various Schools and Hospitals for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO OUR READERS.

As this number is mainly devoted to information necessary for students intending to join one or other of the various medical colleges, and for those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week.

GRATUITOUS COPIES.

A very large number of copies of this issue are being sent gratuitously to all the educational establishments, hospitals, reading-rooms, clubs, and large hotels, in the United Kingdom, and to a large number in America, India, the Colonies, and on the Continent; should any of our readers desire to present a copy to a patient or friend who contemplates sending his son to a medical school, our publisher will be happy to supply him with a duplicate free of cost on receipt of address.

Dr. L.—The treatment of multiple warts of the fingers is as varied as most treatments for simple ailments. Have you tried lime water? The patient to drink a wineglassful of lime water with each meal. At any rate it can do no harm, and we should be interested to hear if you get any good results.

R. D. M.—Radium is still being used medicinally, and the demand for its use as a therapeutic agent has led the management of the Imperial Uranium Works, in St. Joachimsthal, Bohemia, to construct a special laboratory for the industrial production of radium compounds. The uranium ores of this locality contain higher percentages of the element than any other known deposits. The ores and the residues from the uranium extraction have hitherto been treated chiefly at Paris, where the method for isolating the minute traces of radium was perfected by Madame Curie and her husband. There will be manifest advantages in carrying out the extraction at the place of origin, in view of the enormous amounts of rock required for the production of a tiny fragment of a radium salt. Interesting likewise is the fact that an extensive sanatorium is being erected in the same locality, where patients can take baths in the water pumped from the uranium mines. This water seems to be sufficiently charged with radium compounds in solution to exert a distinct therapeutic action, and physicians have already begun to prescribe its use.

Old L. S. A.—The subject of Acroparæsthesia was dealt with at length in the Medical Press and Circular of April 10th, 1907, in a clinical lecture by Dr. A. T. Whiting. If you refer to that number you will find all the points on which you require information discussed.

Devonian.—Webbed fingers are always congenital, and in a simple case can be easily dealt with, *i.e.*, when the phalanges are not united. Simple incision of the web is often followed by reunion of the web, but a careful plastic operation, under an anæsthetic, the divided parts being sutured, will generally be successful.

Vacancies.

Durham University College of Medicine.—Demonstrator of Physiology. Salary, £200 per annum. Applications to Professor Howden, Durham College of Medicine, Newcastle-upon-Tyne. (See advt.)

Cambridgeshire, etc., Asylum.—Second Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors.

Torbay Hospital, Torquay.—House Surgeon. Salary, £100 per annum, with residence, board, and washing. Applications to H. J. Packe, Secretary.

London Temperance Hospital, Hampstead Road, N.W.—Resident Medical Officer. Salary, £120 per annum, board, lodging, and washing. Applications to A. W. Bodger, Secretary.

Gravesend Hospital.—House Surgeon. Salary, £100 per annum, with board and residence. Applications to A. E. Thomas, Secretary.

West Herts Infirmary, Hemel Hempstead, Herts.—House Surgeon. Salary, £100 per annum, with rooms, board, and washing found. Applications to the Rev. W. T. T. Drake, Boro' Gate, St. Albans.

Newcastle-upon-Tyne City Hospital for Infectious Diseases.—Resident Medical Assistant. Salary, £104 per annum, with board, lodging, etc. Applications to the Medical Officer of Health, Health Department, Town Hall, Newcastle-upon-Tyne.

Appointments

Dewar, J., M.B., B.S.Aberd., Certifying Surgeon under the Factory and Workshop Act for the St. Margaret's Hope District of the county of Orkney.

Flitcroft, T. E., L.R.C.P.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the North Bolton District of the county of Lancaster.

Glassington, Charles W., M.R.C.S.Eng., L.D.S., Dental Surgeon to the Duke of York's Royal Military School, Chelsea.

Gunn, A. B. M., M.B., M.S.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Westray District of the county of Orkney.

Lawry, Richard Coger, L.R.C.P.Lond., M.R.C.S.Eng., Medical Officer to the No. 1 District and Workhouse, Penzance.

Lawson, Thomas Cornelius, M.R.C.S.Eng., L.S.A., District Medical Officer by the Stratton Union, Cornwall.

Scott, Frederick R., M.B., B.S.Durh., Medical Officer of Tynemouth Workhouse.

Smith, G. McCall, M.B., B.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Strathmiglo District of the county of Fife.

Births.

Carr.—On Sept. 3rd., at Mowmacre, Chesterton, Cambridge, to Dr. and Mrs. Frank Carr, a son.

Corfield.—On Sept. 4th, at Field View, Upper Tooting, the wife of Edward Carruthers Corfield, M.R.C.S.Eng., L.R.C.P. and L.S.A.Lond., of a son.

Drew.—On Sept. 3rd, the wife of Douglas Drew, B.S., F.R.C.S., of a daughter.

Furnivale.—On Sept. 6th, the wife of Captain C. H. Furnivale, R.A.M.C., of a son.

Marriages.

Bruce—Bowden.—On Sept. 3rd, at St. John's Church, Dumfries, Lewis Campbell Bruce, M.D., F.R.C.P.E., second son of Major-General A. A. Bruce, retired Bengal Staff Corps, to Caroline Desborough, elder daughter of the late Major H. G. Bowden, of the 22nd Foot.

Daniel—Bapty.—On Sept. 6th, at Epsom Parish Church, Alfred Wilson Daniel, M.D., son of the late Dr. W. C. Daniel, of The Silver Birches, Epsom, to Lena Gertrude Lucie Lee Bapty, daughter of Samuel Lee Bapty, of Birmingham.

Deaths.

Chaplin.—On Sept. 3rd, at St. Leonards-on-Sea, Sophia Caroline, widow of the late Thomas Chaplin, M.D., of Jerusalem.

Clark.—On Sept. 4th, at Rose Hill, Dorking, Charles Mackinnon Clark, M.D., L.R.C.P., M.R.C.S., aged forty-two.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, SEPT. 18, 1907. No. 12

NOTES AND COMMENTS.

Board of Education and its Medical Staff.

THE Board of Education have certainly got to work, with a celerity unprecedented in the annals of Government departments, in their preparations for administering the Education (Administrative Provisions) Act. Indeed, there can be no doubt that they had their plans and arrangements well in hand before the Bill passed. In selecting Dr. George Newman for the post of Chief Medical Adviser to the Board, Mr. McKenna has made a wise selection. His field of choice was extremely wide, but we fancy it will be generally agreed that Dr. Newman's attainments, experience, and industry in public health and bacteriological work combine to fit him admirably for his new duties. Dr. Eicholz, who has been in the office for many years, will, of course, form one of Dr. Newman's staff, and the Board, it is understood, are anxious to get to work as quickly as possible with what material they have. In advising local authorities how best to proceed with the new task, which it is hoped they will all undertake in earnest, it is exceedingly important, if the medical inspection of school-children is not to disappoint lay administrators, that the more practical side of the work should be brought forward at first, leaving the more academic phases for subsequent consideration. It is difficult to raise popular enthusiasm over minute anthropometric measurements, whereas most people can appreciate the value of ridding children of adenoids or providing them with glasses. To such more tangible aspects of the problem it would be better to pay attention at first.

Deceased Wife's Sister.

IF the old saying *de minimis non curat lex* embalms a salutary principle of law, a still more obvious if less salutary one which shows itself at times, is that people care a great deal more for little laws than they do for great ones. Out of the mass of important legislation passed last session the only Act which has touched the public imagination or fired the pens of the autumn correspondents of the newspapers is the Deceased Wife's Sister Act. Now the question dealt with in that measure is trifling in the extreme. To begin with, women being longer-lived than men, the number of widowers comparatively speaking is small, and of those the number who re-marry is even less, and out of the remainder the ones who were so happy with their first wife as to wish to embrace another of the same family might be counted as single spies rather than in battalions. As the whole number of such in the country must have been waiting some time to have their marriages legalised, and as up to date only two couples have given notice of their intention to avail themselves of the privilege it really is a case of *de minimis*. However, an ecclesiastical point being touched, the whole country is divided into two camps waging religious war with all the fervour of Turks and Crusaders, and any stick being good enough to beat an infidel with, the anti-aunt champions have not failed even to invoke the physiological argument. This seems to run as follows: That on the *una caro* principle, if a man marries his sister-in-law and has children they will be liable to all sorts of degenerations and abnormalities.

Her Physiological Immunity.

IF the argument is to be pleaded seriously, we should demand some sort of evidential basis, but, needless to say, none is forthcoming. As in all "anti" campaigns, assertion and asseveration are more important that fact. Now presumably the greatest blessing about the Deceased Wife's Sister Act is that it will save an amount of valuable time every session, and that it has transferred the cock-pit of the dispute from the floor of the House to the lean columns of the autumn Press. But as to physiological argument, the "one flesh" principle will not hold water for a moment, whatever religious or even moral support it may have. Most practitioners have seen the children of first cousins presenting some of the minor if not the major stigmata of degeneration, and these no doubt are the result of consanguinity, although marriage in that degree has always been allowed by both Church and State. The prohibition of cousin-marriages is a matter which, if it came to the point, would derive an appreciable amount of physiological support. The suggestion, however, that a husband and wife in course of time acquire some of each other's characteristics, and that a husband, by marrying a sister-in-law, can reproduce those characteristics with added force in the offspring, is the most fantastic nonsense that good people in want of an argument ever strained out of books they do not understand. Medical men, as such, having no interest in the question but a physiological one, can nevertheless, assure the disputants that they had better confine their polemics within the bounds of Statute and Canon law, and leave alone the science of heredity against which there is such a multitude of real offences in civilised society that there is no need to import fanciful ones.

Dentistry a la "Daily Mail."

Strange things happen in the calling of medicine, but if the *Daily Mail* is to be believed, still stranger ones happen in the practice of dentistry. It is asserted by the New York correspondent of that journal that one George Davis, aged thirty-eight, who died recently in the County Hospital of Chicago, was diagnosed to have suffered from a broken neck. The symptoms complained of during life were pain in the neck and paralysis of the right arm, and they apparently came on after a visit to the dentist's. Davis had called on that practitioner with a view to having a painful tooth removed, and the molar being firmly set, the dentist had used a series of jerks to loosen it. The physicians who saw the patient subsequently believed that the neck had been dislocated by this treatment, and death occurred in due course. The account adds: "The name of the dentist is not known," and one is quite prepared to believe this modern Hercules will remain incognito. Indeed, it would be a pity if he did not, for he would be sure to dispute the impeachment, and if he was believed, the beautiful story with its pregnant suggestiveness would be spoiled. Let us take the innominate dentist on trust, and add this catastrophe to the list of surgical dangers attending minor operations, for its like we shall never look on again. What greater lesson could we have of the pitfalls that attend apparently simple operations or of the frailty of cervical vertebræ?

Hygienic Sheets.

There are so many hidden dangers to health in this world we have the misfortune to live in, that it is really questionable if some penal restriction should not be applied to scaremongers. These gentlemen go about trying to find some new horror wherewith to make our flesh creep, and the amount of ingenuity they expend in the pursuit of their avocation is astonishing. The last, and we imagine the silliest, of these menaces to health has been discovered by one Mr. Shuttleworth-Brown, inventor of the new hygienic bed-sheet. We all know Mark Twain's calculation showing the tremendous risk run by people who sleep in beds, but, apparently, the hygienic sheet would reduce this danger to the comparative security enjoyed by people who travel in submarines or dirigible balloons. The real danger of sleeping in bed consists in the erroneous notion possessed by servants that sheets should be turned. Of course, nothing of the sort should be done. If the sheet is turned, the particles of epithelium and so on that are rubbed off the skin get into the bedding, whereas if the sheet is never turned the epthelium remains where it was. Consequently, Mr. Shuttleworth-Brown has presented to the, world his new sheets, which have a tuck in them so that people may tell whether they have been turned or not. So that any servant who hereafter turns a sheet will have short shrift and no benefit of clergy. How the new hygienic sheet will catch on amongst those who prefer extravagant idiocy, we cannot say, but we should imagine that a sheet that would not wash would have an even better chance of popularity among them. The drivelling folly that is perpetrated under the name of hygiene is enough to make angels weep and all sensible people shudder at the very mention of the word.

Manifestations of Wisdom.

Wisdom is justified of her children, but since the inauguration of the era of manifestoes, many of the children of light seem to have lost touch with their notion of the eternal fitness of things. Or is it perhaps that they have only lost touch with their sense of humour? Drink having been manifestoed from two points of view, it is the turn of food. The week before last we published a strange and naïf document of a pro-vegetarian tint, and this week it is our privilege to give publicity to another ingenuous expression of opinion on a similar subject. The signatories of the latter draw attention to the interesting fact that "insufficient and improper food is a prominent factor in the causes to which degenerative tendencies might be ascribed." Surely these gentlemen might be a little bolder and omit the subjunctive. We fancy there would be found few to quarrel with them if they took their courage in both their hands and asserted point blank that insufficient and improper food does actually produce degenerative tendencies. Sam Weller, when he realised Mr. Pickwick's soft-heartedness, exclaimed in admiration that his master's heart had been born later than his body, and when we read this latest of manifestoes we begin to wonder if signatories' hearts are not similarly afflicted with an excess of juvenility. Is it really worth while to appeal to the "Lord Mayors and Mayors of London and of other cities and towns, all municipal authorities, and other good folk, to direct attention to this important subject?" In a word, might it not be taken for granted that if the people sin in eating insufficient and improper food, they probably do so not so much through ignorance as that either they have not enough money to buy sufficient food, or that they have too much money and so can afford improper food? At any rate, we would venture to throw out the suggestion for what it is worth.

LEADING ARTICLE.

A MEDICAL DEPARTMENT IN THE BOARD OF EDUCATION.

The gradual extension of the scientific method in the working of national administration is a process which, though at times slow and halting, may be regarded nevertheless as inevitable. So far as State education is concerned it is only within the last few years that the greatness and complexity of the health problems involved in that system have been recognised. At the present moment these questions are engaging the attention of "experts," medical, sociological, educational and political, in all the nations. Clearly, the subject is so far only partly explored, and investigators are faced with years of patient labour before facts can be properly ascertained, and the kaleidoscope of school life reduced to a plain presentation of cause and effect capable of statement in the form of a general law. In our own country it is reassuring to find that we are taking steps to bring ourselves up to the level of the sanitary standards enforced in the schools of other civilised nations. Of all the social measures passed by the Government during the Parliamentary Session that has recently come to a close, there is probably not one of greater and further-reaching importance than the Education (Administrative Provisions) Act, whereby provision is made for the compulsory medical inspection of children in elementary schools, and power is given to local authorities to make arrangements for medical treatment, as well as to establish what are known as play centres and vacation schools. It is now officially announced that the Board of Education have decided to establish a Medical Department for the purpose of giving them advice and assistance in the discharge of the new duties imposed by the above-mentioned Act. The chief duties of the Board in this direction will consist in advising and supervising local education authorities as to the manner and degree in which those authorities carry out this medical inspection; in giving such directions as may be necessary regarding the frequency and method of such inspection in particular areas, and in considering and sanctioning such arrangements as may be proposed under the Act by individual authorities for attending to the health and physical condition of the children. The Board will also collect and collate the records and reports made by the authorities in the process of carrying out the new duties imposed by the Act, and will issue an official annual report on the subject.

The national importance of this new departure it is hard to over-estimate. It provides in some sort a guarantee that in future the State will discharge the duty of safeguarding the health of the individual child. At length the voice of the reformer has carried conviction to the legislature, and in future the halt and the maimed, the crippled and the defectives of all kinds will be carefully tended from the first day of their entrance into the elementary schools. It follows infallibly that such a work carried out systematically and scientifically in the schools must go far in stemming the unnecessary waste of health and life that is steadily exhausting the vitality of the nation. It is obvious that a great task lies before such a Medical Department as that now added to the Board of Education. The special science it is called upon to administer is still in its infancy, and a suitable administrative machinery will have to be created. We understand that the precise details of the organisation and personnel of the new Department have not yet been determined. At the same time we are glad to hear, on good authority, that the work will be mainly that of a central controlling body, leaving wide powers of individual action to local authorities. Meanwhile, the President of the Board of Education has appointed Dr. George Newman, the well-known Medical Officer of Health of the Metropolitan Borough of Finsbury, to be Chief Medical Officer of the Board. He has an able lieutenant in the person of Dr. Alfred Eicholz, who has for nine years been on the Board's staff as Medical Inspector of Schools. It is further understood that the Board of Education will issue shortly to the local education authorities a circular setting forth their new duties in the matter of the medical inspection of school children. In conclusion we may reiterate our opinion that the creation of the new Medical Department marks one of the most important departures in public health that have been adopted by the British Government.

CURRENT TOPICS.

An Imperial Vaccinationist.

The news that an extensive smallpox epidemic has broken out at Vienna naturally raises some sort of wonder that in the twentieth century it is possible for such a thing to occur in a civilised country. It is a simple scientific proposition which asserts that any community protected by vaccination and re-vaccination has no need to fear the inroads of smallpox. Nor is it less self-evident that the terribly fatal infection of that malady runs riot when introduced into a population partially or wholly unprotected by vaccination. From these premises it follows that the Viennese, being seriously invaded by smallpox, must be inefficiently protected by vaccination. Precisely the same inference might have been made upon equally infallible grounds when London was ravaged by smallpox some years ago, when the disease picked out and decimated the unvaccinated population. Yet it is this vulnerable material that the anti-vaccinationist, in his blind fatuousness seeks to multiply, regardless of the deadly peril to which he is thereby exposing his countrymen. Were anti-vaccinationists to have their way the population of the United Kingdom would soon be reduced to the helpless state of a tribe of South Sea Islanders in face of an outbreak of smallpox. So far as orthodox medicine is concerned in Vienna, it has found a staunch supporter in the person of the Emperor Francis Joseph. At the advanced age of 77 years his Majesty was, naturally, at first somewhat loth to follow the advice of his medical advisers, but later allowed himself to be vaccinated. This act, simple in itself, is worthy of being recorded as characteristic of a king, who by a life of self-sacrifice and resolution, has raised his kingdom to a first rank among the nations of the world. Nor do we doubt that under similar circumstances our own countrymen would find themselves stimulated in no less a degree by kingly example.

An Echo of a Famous Manifesto.

Some months ago the wonder of the community was excited by an extraordinary manifesto in favour of alcohol, signed by a number of prominent medical men and published in the form of a letter by a prominent medical journal. That document was followed by a counter-manifesto from The Medical Press and Circular, signed also by various distinguished men in the profession, and stating that alcohol was unnecessary to mankind under ordinary conditions, while at the same time it had a restricted field of usefulness as a medicine. The points thus raised were taken up widely by the general Press, and have since been followed up with unremitting energy by the advocates of total abstinence. While there can be no question as to the absolute *bona fides* of those who signed the original manifesto, there is some reason to suspect that they have been made in some obscure way the catspaws for those interests on the commercial side of alcohol. At any rate, it has been often reported that their manifesto has been circulated by societies devoted to the brewing and distilling trades. The unwisdom of signing any public declaration of the kind is shown by the latest attack upon its character. Last week a lecturer in Birmingham is reported to have said that he had obtained the shareholders' lists of a number of companies and from a perusal of them he had discovered that three of the medical signatories of the original company held brewery shares. Although the gentleman in question, Mr. Tennyson Smith, made his statment to a public audience, we cannot but think he is labouring under a misconception of some kind. The incident, however, shows the extreme caution that should be exercised by any member of the medical profession who is invited to sign declarations of faith that may possibly be appropriated by unscrupulous persons for private ends.

Economical Poor-Law Dentistry.

THE boarding-out system applied to Poor Law children, excellent in itself, nevertheless requires constant supervision to prevent abuses. At Bristol, the homes in connection with boarded-out children have been reported upon by Dr. Fuller, the Local Goverment Board Inspector. The portion of his report dealing with dental matters deserves careful attention. He found that the teeth of many children were in a neglected condition, that carious teeth were left unheeded, that extractions were unnecessarily frequent, and that no provision was made for scaling the teeth. This state of affairs, the Inspector remarks, is hardly to be wondered at when the contract with the dentist is examined; for it can hardly be possible to ensure proper stopping at one shilling per tooth, especially when it is noted that the stopping is to be done with gold amalgam. In view of this report the Bristol Guardians have arranged for a routine examination of the children's teeth once every three months. The necessity of reporting adversely upon contracts of this nature could possibly be avoided were a more rigorous examination of the terms of such agreements carefully made by the Local Government Board in the first instance. Bristol has a good record as regards Poor-Law administration, and in this instance has shown a commendable desire to carry out its duties conscientiously.

Proposed Public Health Parliament.

THE activity shown nowadays in the various departments of public health science is no less conspicuous than it is unflagging. Hardly have we settled down after the recent Public Health and School Hygiene Congresses than we are faced with another excellent enterprise of a similar complexion. The proposal came in the first place from Dr. Armstrong, the well-known medical officer of health for Newcastle-upon-Tyne. His original idea was to summon a national congress to frame legislative suggestions for the consideration of Parliament with regard to the scourge of tuberculosis. From that nucleus the scheme has grown so as to include other urgent problems, for instance, infant mortality, milk, and meat supplies, the housing of the masses, the drink problem, the disposal of sewage, and so on. Dr. Armstrong suggests that delegates should be elected by constituted authorities on a basis of population, that they should meet in London as a representative Parliament, and frame measures for the guidance of the national Parliament at Westminster. The suggestion is altogether admirable and should the financial and other difficulties of organisation be satisfactorily surmounted, there is every prospect of its adding greatly to the establishment of public health as one of the chief factors in the world's progress.

The Emotional Theory of Infection.

LADY CARLISLE is an Englishwoman of whose kind-heartedness and fine philanthropy we may as a nation well be proud. Her attitude as regards infectious diseases, however, is one which, although inspired by motives of the highest and purest nature, are nevertheless, in our opinion, so prejudicial to the public interest that we venture to offer some sort of gentle remonstrance. Recently the Malton Rural District Council complained that infection was carried by poor children brought into their district by charitable agencies from Leeds and Bradford. Lady Carlisle has written to the *Leeds Mercury* a letter in which she practically declares her belief that there is no truth in the "infection scare." She draws a vivid picture of the joy of "the little ones as they ramble to and fro during the sunny summer days, gathering up stores of health and good spirits, and measuring in their quick little town brains visions of beauty," and so on. That is all very well, but the mere expression of Lady Carlisle's disbelief in infection does not lessen the virulence of the germs of diphtheria, measles, whooping-cough, tuberculosis, and so on, that are conveyed into "the cottage homes of this beautiful district" (Malton), by little infected town bodies. Surely the modern doctrine of the responsibility which forbids the individual to injure others by the spread of personal contagion justifies the attitude of the Malton Council. If poor children are to be imported thither from Leeds and Bradford, then it is imperative on those who send them to ascertain that they are free from infectious disease. The fatalism of the poor is a great obstacle in the way of preventing the spread of infectious diseases, but, happily, educated persons, as a rule, are alive to the scientific aspects of prevention.

Chicago in England.

THERE were many people who, at the time or the revelation of the Chicago horrors a year of two ago, had more than a suspicion that, if all were known, the conditions in many London factories were not such as to allow of our adopting a very superior air toward our American cousins. It is always much easier, however, to express indignation at atrocities far away than to search out injustices in the next street. A report recently issued by the Industrial Law Committee, though it does not make any sensational revelations such as came from Chicago, nevertheless shows plainly to what tyranny women and girls employed in the smaller factories of London are liable to be subjected. It is true that the Factory Acts have done much for their protection, but the great difficulty is to bring the law to bear on a particular injustice. Inspectors are not ubiquitous, and employers are often adept in evading the law. A girl who draws the attention of the inspector to a breach of the law is almost certain, directly or indirectly, to lose her employment. Several cases of this sort are quoted. Particulars, too, of a shocking nature are given as to the conditions under which many of these girls in the East End have to labour. In a box factory, seventy girls work in a varnishing room whose windows are never opened for fear of dust. In dressmakers' shops the hands may have to work from early morning till late in the afternoon in rooms unventilated and unheated, without, for seven or eight hours at a stretch, any break for meals. These are the kind of cases which the Industrial Law Committee investigate, and from their report it is evident that they are at no loss for material on which to exercise themselves.

Mr. Haffkine and India.

We are very glad to see from a leading article in *The Times* of September 7th that that journal definitely espouses the cause of Mr. Haffkine. In The Medical Press and Circular, among other journals, the injustice done to that eminent scientist has been the subject of strong protest, and we warmly welcome the strong influence of *The Times* on the same side. We agree with our contemporary that the Indian Government had a difficult decision to make and that they were bound to attach great weight to the advice of the experts, but now that it has been shown by the clearest evidence available that Mr. Haffkine was in no way responsible for the unhappy Mulkowal incident, the least that can be expected is that Mr. Haffkine shall be reinstated in his old post. It is less than justice to offer him, as Mr. Morley has told us the Government have done, an indefinite engagement carrying no specified status, for Mr. Haffkine might find himself in some invidious position from which he could not easily extricate himself if he accepted it. If a mistake has been made—and even the most official mind must admit that such has been the case—surely only complete reparation can repair the harm that has been done. We can hardly believe that the Government of India intend indefinitely to stiffen their backs, but if they do, other means must be employed to show that instructed public opinion in this country cannot be denied its right of seeing that justice is done in the public services.

PERSONAL.

The King has been pleased to give and grant unto Bryden Glendining, Esq., M.B., Physician in attendance on her Majesty the Queen of Spain, his Majesty's Royal licence and authority that he may accept and wear the Insignia of Caballero of the Order of Carlos III., conferred upon him by his Majesty the King of Spain, in recognition of valuable services rendered by him.

It is expected that the new buildings of the Royal Army Medical College in London, now nearly arrived at completion, will shortly be opened by H.M. The King.

Dr. J. T. Wilson was president of the Congress of the Sanitary Association held in Aberdeen, and delivered the opening address.

Mr. Alfred H. Tubby takes the chair at the dinner of the Westminster Hospital Medical School on October 3rd.

Dr. Alfred Eicholz has been appointed to the staff of the new medical department of the Board of Education.

Captain W. H. S. Nickerson, V.C., M.B., R.A.M.C., has been appointed Sanitary Officer of the Northern Command.

Sir Herbert M. Ellis, Director-General of the Medical Department of the Royal Navy, will preside at the St. George's Hospital dinner on October 1st.

Major Ronald Ross, F.R.S., Professor of Tropical Medicine at Liverpool University, will distribute the prizes at the opening of the Leeds Medical School on October 1st.

Sir Almroth Wright delivered the inaugural lecture of the post-graduate medical classes at the Royal Infirmary, Glasgow, his subject being "The Principles of Vaccine-Therapy."

Mr. J. C. McWalter, M.A., F.F.P. & S.Glas., M.D. Brux., D.P.H., Barrister-at-law, has been appointed Examiner in Medical Jurisprudence to the Apothecaries' Hall.

Dr. George Newman, F.R.S.E., D.P.H., Medical Officer of Health for Finsbury, has been appointed Chief Medical Officer to the Board of Education.

The long-service medal has been awarded to Surgeon-Major Ernest W. Barnes, of Liverpool; a well-earned recognition of his long and energetic connection with the volunteer force.

The Royal Commission on Mines have appointed Dr. A. E. Boycott, M.D., of the Lister Institute of Preventive Medicine and Guy's Hospital, to make an investigation with a view to determining whether there are any indications of the disease known as ankylostomiasis (miner's worm) in coal mines in Great Britain.

On October 4th, Sir Samuel Wilks will occupy the chair at the first meeting of the Guy's Hospital Physical Society, at the opening of the session, when Dr. G. A. Gibson is to read a paper, entitled "Past and Present."

It is notified in the *Gazette* that the King has nominated Mr. David Caldwell McVail, M.B., to be, for a further period of five years from October 28th, 1907, a member of the General Council of Medical Education and Registration of the United Kingdom, for Scotland.

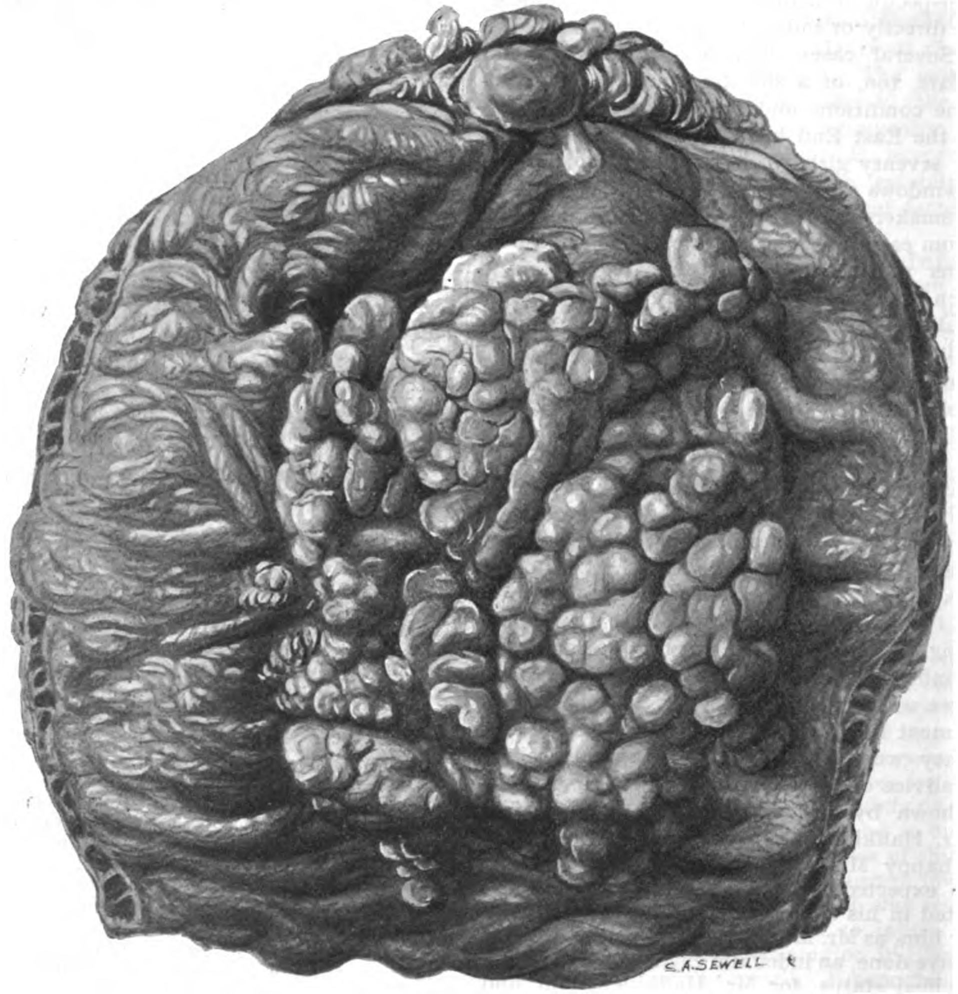
Mr. James Burdett Moxon, of Brigg, Lincolnshire, surgeon, one of the oldest medical practitioners in England, who died at the great age of 95, left estate of the gross value of £1,113 11s. 9d., of which £1,095 11s. 8d. is net personalty.

A Clinical Lecture
ON
CANCER OF THE RECTUM. (a)

By R. ATKINSON STONEY, M.B., B.Ch., F.R.C.S.,

Surgeon to the Royal City of Dublin Hospital; Lecturer on Surgery at the Royal Medical Services School, &c.

I HAVE chosen this subject for lecture this morning for two reasons: first, the rectum is one of the commonest positions in the body to be attacked by cancer; secondly, this is one of the forms of cancer which frequently remains unrecognised till late, and this in spite of the fact that probably at least ninety per cent. of these growths are palpable by the finger examining the rectum, even at an early stage. I hope before I have finished this morning to explain why this disease is so often overlooked for a long time, and to put you on your guard, so that you may make an early diagnosis in these cases.



Specimen (actual size) from Case III. The rectum with the anal end uppermost has been opened to show the large cauliflower-like growth on the posterior wall.

We have had three cases of rectal cancer in these wards within the last few months, and as they all show some points of special interest I shall commence by briefly recalling to your remembrance the main facts of these cases.

CASE I.—R. R., male, æt. 75, was admitted to this hospital on November 8th, 1905, suffering from a tumour of the rectum. He gave a history of pain in the back, increased by defæcation and difficulty in getting his bowels to move, with occasional traces of blood in his motions for some months. On rectal examination a large, irregular ulcer with thickened, hard, everted edges was felt on the posterior wall of the rectum, within about two inches of the anus. It was just possible to pass the finger to the upper limit of this ulcer. An operation was performed on November 25th, and the rectum with the growth was removed. It was found impossible to bring the upper end of the rectum to the anus, so a sacral anus was made, and the whole of the lower part of the bowel removed. The patient was discharged from the hospital a month later with the wound completely healed.

(a) Delivered at the Royal City of Dublin Hospital on Thursday, December 13th, 1906.

CASE II.—D. B., æt. 48, male, was admitted on March 18th, 1906, complaining of piles, alternating constipation and diarrhœa and pain in the region of the sacrum. On rectal examination a large mass was felt filling the upper part of the pelvis but no growth could be felt in the rectum. The following day the patient was examined under an anæsthetic with the electric sigmoidoscope; after it had been passed for about 6 inches without any growth coming into view, the patient coughed and the instrument appeared to move suddenly upwards, but no growth was visible; he was then returned to bed. Late that night the patient developed symptoms of commencing general peritonitis, and on opening the abdomen early the next morning diffuse peritonitis was found, evidently starting from a large foul-smelling pelvic abscess which had burst, probably during the examination on the previous morning; the adhesions in the pelvis were so numerous and complicated that it was difficult to make out where the abscess came from, but it was evidently in direct connection with the bowel, and there appeared to be a growth of the upper part of the rectum. The whole length of the colon was packed with scybalae, so a colostomy was performed and the abdomen washed out, and the pelvic abscess drained. The patient recovered from the peritonitis, but though he lingered for a month, the pelvic abscess continued discharging, and he died on April 20th. At the autopsy the whole pelvis was full of stinking pus, there was a large malignant growth of the upper part of the rectum, and a communication between the lumen of the bowel above the growth and the abscess cavity.

The third case you see before you, the patient, A. R., male, æt. 58, was sent up to the medical wards of this hospital from the country on October 3rd, 1906, supposed to be suffering from piles and some liver trouble. On examination after admission he was found to have a growth in his rectum, and was at once transferred to the surgical wards. On rectal examination a very large cauliflower-like growth was felt on the posterior wall of the rectum within three quarters of an inch of the anus, the finger could not reach its upper border, and the growth appeared fixed. On October 6th a colostomy was performed, and the rectum and pelvis examined at the same time. No enlarged glands could be felt, and the growth did not appear to have extended beyond the rectum. The intestine was opened on the 10th, and on the 27th the rectum was removed. The wound is now practically healed, and those of you who saw the patient on admission will notice the great improvement in his appearance, he has put on over a stone since the last operation, and is almost ready to return home. (*a*)

These three cases illustrate in a very beautiful manner the three types of cancer of the rectum proper which may occur.

(1) The ulcerous variety—this commences as a nodular growth or plaque involving part only of the circumference of the intestine. Sooner or later this breaks down and forms a typical, malignant ulcer with everted, thickened and hard edges, it usually grows slowly, and may not produce marked symptoms of obstruction. The first case was a very good example of this form.

(2) The cauliflower variety—this also starts as a nodular growth, but it extends fairly rapidly and finally forms a large, rough, irregular, cauliflower-like growth projecting into the lumen of the rectum, but it does not tend to ulcerate to any great extent; it may produce marked symptoms of obstruction. The third case was a very good example of this form, and here you see the actual specimen. (See illustration). Both of these two types usually grow from the posterior wall of the rectum.

(3) The annular variety tends early to involve the whole circumference of the gut, and as a rule ulcerates early, and by its contraction causes a well-marked constriction of the canal, giving rise to distinct obstructive symptoms, and sometimes leading to a perforation of the dilated bowel above. The second case more nearly approached this variety than either of the other two.

The symptoms of cancer of the rectum are often extremely vague, and are frequently put down to piles in the earlier stages. Pain is usually one of the first symptoms; at first it may be felt only during and after defæcation, or there may be merely a feeling of weight and dragging in the lower part of the back, and after defæcation the patient may feel that there is still something more to be passed. Later, when the growth ulcerates, there may be some blood with the motions; this is very rarely copious, but is, as a rule, only a streaking or staining of the motion with blood. When the tumour commences to cause obstruction, a very definite train of symptoms arises—there is tenesmus and straining and alternating constipation and diarrhœa. The latter is a spurious diarrhœa, and consists of fæcal-stained mucus; it is brought about as follows:—the growth causing obstruction leads to a retention of the fæces above the stricture, this leads to irritation of the mucous membrane with an outpouring of mucus, which collects and dissolves some of the hard fæces, and then this fæcal-stained mucus trickles through the stricture. Hæmorrhoids may be caused by the pressure of the tumour and the straining it leads to. In fact the onset of hæmorrhoids after the age of 40 or 50, with the passage of small quantities of blood, with alternating constipation and diarrhœa, may be looked upon as pathognomonic of cancer of the rectum, and should always lead to immediate digital examination of the rectum. This digital examination is the final test to which all suspected cases must be submitted, and as I mentioned before in a very large proportion of the cases the growth can be felt. It may also be seen by the proctoscope or sigmoidoscope. If the growth attacks the anterior wall of the rectum it may spread to the bladder and give rise to further symptoms, pain on micturition, discharge from the rectum whenever the bladder is emptied, or finally to a recto-vesical fistula. In the second

---

(a) The patient returned to the country on January 3rd, 1907, with the wound completely healed, only a very small quantity of mucous coming daily from the lower end of the rectum which opens in the sacral region, and an artificial anus in the inguinal region over which he has some control.

case the patient met me one day in the street and said he must get something done, as he was suffering from piles. I advised him to come into hospital at once; but I did not see or hear of him again for over six months, when he told me the piles were worse, and on questioning him he told me he suffered from alternating attacks of constipation and diarrhœa, the latter being in the form of very frequent motions, when only a very small quantity was passed. This made me suspect cancer, and I insisted on his coming into hospital the next day for examination. In the third case the patient was treated in the country for several months for piles and liver trouble, the symptoms in reality being caused all the time by the growth in the rectum. These two cases should emphasise the fact that one must never be satisfied with making a diagnosis of hæmorrhoids in an elderly patient without a digital examination, or precious time may be lost.

Unfortunately, cancer of the rectum still gives very bad results after operation, and this in spite of the fact that the disease occurs in an organ which is easily removed completely, and that it tends to remain limited within the muscular coats of the rectum for a considerable period. These bad results can only be explained by the fact that most of the cases are operated on too late.

Considering now the question of what the surgeon can do for a case of cancer of the rectum, the ideal treatment is, of course, complete removal of the disease with restoration of the continuity of the alimentary canal and a preservation of the sphincteric apparatus of the rectum. For this to be possible the following points must be fulfilled :—removal of the growth must not involve removal of the anal canal, or at least the external sphincter must be preserved. After removal it must be possible to free the upper end of the bowel sufficiently to bring it, without tension, to the lower part. Frequently this ideal form of operation is not possible, and then one must be satisfied with a sacral anus, over which the patient has little or no voluntary control. This is more liable to occur in the case of males than females, as in the former the rectum is usually shorter and has not so long a mesentery.

The operations described for the removal of cancer of the rectum are generally divided into three types, according to the point from which the growth is attached :—(*a*) Perineal; (*b*) sacral; (*c*) and combined abdominal and sacral.

The perineal operation is rarely done, as it is only suitable to cases where the growth is situated very low down, involving really the margin of the anus or the anal canal.

The sacral is the form of operation applicable to the majority of cases. Here the rectum is attacked from behind, after removal of the coccyx and the lower one or two pieces of the sacrum. The removal of the sacrum must never extend above the level of the third sacral foramina, or the third sacral nerves will be cut, and as they supply both the rectum and the bladder, incontinence of both urine and fæces will result from their destruction. In some cases, especially where the growth is situated high up, it may be better to start the operation by an abdominal incision, through which the bowel is divided above the growth, the rectum freed and the superior hæmorrhoidal vessels tied, and the operation may be completed by an incision in the sacral region.

The advisability of performing a preliminary colostomy in the left inguinal region is a disputed question. The following are its disadvantages :—(*a*) it necessitates two operations instead of one; (*b*) it is difficult or troublesome to close this artificial anus if at the second operation it is found possible to unite the two ends of the rectum and preserve the normal anus; (*c*) it may prevent the upper end of the rectum being sufficiently freed to bring it down to the lower end; (*d*) there is a more or less sentimental objection to the presence of an artificial anus in the inguinal region. On the other hand the advantages are as follows: —(*a*) it relieves any obstruction that may be present, and may allow of the general health of the patient being greatly improved by good feeding before the more severe operation of removal is undertaken. This point was well exemplified in the last case, where it was not thought safe to embark on an extensive operation owing to the very weak condition of the patient on admission into hospital; (*b*) it allows a thorough examination to be made of the tumour and its connections, and shows the presence or absence of enlarged glands or secondary growths in the liver; (*c*) it allows of careful cleansing of the rectum by washing out the lower bowel before the second operation, and therefore diminishes the risks of sepsis during the operation; (*d*) it prevents the passage of fæces through the operation area, and therefore diminishes the risk of the occurrence of sepsis after the operation; and this is one of the most important causes of the operative mortality; (*e*) lastly, if at the second operation it is found impossible to unite the two ends of the bowel, an inguinal anus is more convenient for the patient than a sacral one, and after a time the patient may gain some, if not complete, voluntary control over it, if the bowel has been brought through the separated (not cut) fibres of the abdominal muscles.

As regards cases where the growth has extended beyond the limits of removal, by the performance of a timely inguinal colostomy, not only may the patient's life be prolonged but in addition his pain and discomfort may be greatly reduced by diverting the flow of fæces from the ulcerated surface, and by the topical application of soothing or antiseptic lotions. Again, the possible onset of acute obstruction, a common fatal complication, is prevented. If this operation is decided on, it should be done as soon as possible, and the surgeon should not wait for the onset of symptoms of acute obstruction, as colostomy, which normally is a comparatively trifling operation, is under these circumstances attended with a considerable mortality.

The last point we have to consider this morning is that of prognosis. As I have already told you this is unfortunately not as good as one could wish, either as regards immediate or remote prospects. There is not only a considerable mortality from the operation but there is also a large number of recurrences, not usually in the form of local growths, but more often as secondary deposits in distant fiscera, especially the liver.

The main dangers of the operation are :—(*a*) Shock from the severity of the operation in a patient who is worn out from pain, loss of sleep, septic absorption from the ulcerated bowel and inability to take sufficient nourishment, or possibly the complication of acute obstruction. This danger can be largely overcome by careful treatment of the patient before operation, and in some cases by the performance of a preliminary colostomy; (*b*) the onset of peritonitis due to infection of the peritoneal cavity, either at the operation or immediately afterwards, as in the sacral operation the peritoneal cavity is practically always opened. This danger may be almost entirely eliminated by care during the operation, and by stitching the peritoneum around the upper end of the bowel, so as to shut off the general peritoneal cavity; (*c*) sepsis from infection of the large wound resulting from the operation or sloughing of the bowel; this may be largely, if not altogether, avoided by the technique of the operation, by careful drainage and packing of the wound, and by the prevention of tension on the upper end of the bowel and careful preservation of its blood supply, also, as I mentioned above, by the performance of a previous colostomy.

The dangers of recurrence can only be lessened by careful and complete removal not only of the rectum, but also of the tissues between it and the hollow of the sacrum, and by the earlier recognition of the disease, which will allow of operation being performed before infection of the glands and liver has occurred.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Sydney Stephenson, M.B.Edin., F.R.C.S., Ophthalmic Surgeon Evelina and North-Eastern Hospitals for Children, Kensington General Hospital, &c. Subject; "Congenital Anomalies of the Eye."*

ORIGINAL PAPERS.

THE JUSTIFICATION FOR

ARTIFICIAL DILATATION OF THE CERVIX

TO HASTEN DELIVERY AT FULL TERM, WITH A DISCUSSION ON THE MOST APPROPRIATE METHOD OF PROCURING THIS DILATATION. (*a*)

By ROBERT JARDINE., M.D., Edin.,

Professor of Midwifery. St. Mungo's College, Glasgow, &c.

In opening the discussion Prof. Jardine said that the first part of the subject, viz., the justification of the operation, need not occupy much time. The operation had been in use for such a long time that it might be maintained that it was justified by use and want. No justification was necessary for an operation which enabled one to save life. Undoubtedly conditions occasionally arose where, in the interest either of the mother or the child, or of both, a quick delivery was necessary, and, if that delivery was to be carried out through the natural passages, artificial dilatation of the cervix was necessary. A case of unavoidable hæmorrhage might be taken as an instance where the operation was called for in the interest of the mother. In the interest of the child the operation was justifiable in a case of prolapse of the cord early in labour when it was impossible to replace and keep the cord up. While the operation was perfectly justifiable under certain conditions it was occasionally done when there were no just reasons for its use. He strongly protested against this.

The most appropriate method of procuring dilatation.—He first described the methods which approach nature's way by means of hydrostatic bags or the vaginal plug. These methods were slow, and uterine action was called into play by them. Of the bags he considered the firm ones, like Champetier de Ribes, to be more useful than the rubber ones of Barnes. He had found the vaginal plug most useful in placenta prævia, but the plug required to be properly inserted or it would do more harm than good.

Manual and bi-manual methods were next described. Manual dilatation was the one most frequently employed, and was most useful when the cervix was soft and partly dilated.

Dilatation by expanding instruments.—These instruments, like Bossi's, acted much like the hand, but the arms were not sensitive and therefore gave no indication when the parts were being torn. These screw instruments required to be used with great care, and at least half an hour ought to be occupied in the operation. If the cervix was not taken up very great caution was necessary.

Cutting methods.—Multiple incision of the cervix, as recommended by Dührssen. The cervix should be obliterated. The number of incisions varied from two to seven. There was risk of the lateral incision extending so as to cause injury to the uterine arteries, and in making the incisions one should avoid the lateral position and especially when making four incisions. The child should be delivered at once, preferably by forceps, and after the placenta was away the cervix should be drawn down for careful inspection. If there was bleeding the incisions should be stitched, but if there was no bleeding stitching was not absolutely necessary.

Vaginal Cæsarean Section.—Dührssen's name was also associated with this operation, but he had not been the first to perform it, although he had been the first to suggest it.

Effacement of the cervix was not necessary and it was preferable that the presenting part should not have been engaged, as version was the method of delivery usually adopted. One very essential condition was that the uterus should be mobile, so that the cervix and lower uterine segment could be pulled well down.

He described the operation, and also Dührssen's perineo-vaginal incision to enlarge the vagina. He did not think this incision necessary, as the vagina could be dilated manually. It had been maintained that the operation was a very easy one and quite free from risks. Occasionally even an expert would find it a difficult operation to perform, and the not inconsiderable number of cases published amply proved that it was not by any means free of risk. The risks were (1) infection, which was common to all operations, but less in vaginal than abdominal ones; to guard against it the strictest asepsis was necessary. (2) Injuries to mother or child; the uterus might be ruptured by extension of the incision, and the bladder had been injured. In regard to the child it had been born dead, and men had even found craniotomy necessary. (3) Hæmorrhage; this was fairly common as the uterus was usually atonic; in all cases it was necessary to be prepared to tampon. He considered that vaginal Cæsarean section was an operation for experts in vaginal surgery, and not one which an ordinary general practitioner could undertake.

(a) Abstract of Opening Address for discussion, Section of Gynæcology, Exeter Meeting, British Medical Association, 1907.

In conclusion, Prof. Jardine said that in deciding on the proper method to adopt the attendant had to consider the condition of the cervix, and also the amount of his experience. If he were an adept in vaginal surgery he would probably prefer vaginal Cæsarean section in all cases in which there was likely to be difficulty in dilating the cervix, but if he had had no experience in that form of surgery, in the interest of his patient, he should adopt one of the other methods, or else call in the assistance of an experienced colleague who could undertake the major operation of vaginal Cæsarean section. In reference to this operation in cases of placenta prævia he was of opinion that, like ordinary Cæsarean section, it was quite uncalled for, as better results could be got by other methods.

CONTAGIOUS DISEASES AND SCHOOL ATTENDANCE. (a)

By SIR SHIRLEY MURPHY, M.R.C.S.,
Medical Officer of Health.

THAT attendance at school should be compulsory is inevitable under the conditions of our civilisation, that this attendance involves increased risk of exposure to infection is undoubted, hence the duty of the State to protect the child from risks incidental to an act of enforced obedience is a moral obligation. Our object in meeting in this room is to endeavour to learn how this protection may be best afforded with the least interference with the primary intention of the child's attendance at school, or how this primary intention may be best effected under conditions which reduce to a minimum the risk to which the school-attending child is exposed. In our study of this subject we are at once confronted with the fact that the risk of infection to the school child in the school is only part of the whole. In endeavours to control the spread of infectious disease in the school it is impossible to ignore the conditions which prevail in the home. In efforts to limit the occurrence of infectious disease in the home we must have regard to the opportunities of infection which occur in the school. In England, until recently, the Education Authority has been separate from the Health Authority, and difficulties which have stood in the way of organised administrative effort have been great. Probably nowhere were the results more manifest than in London during the epidemic of diphtheria which prevailed, especially in the six years 1892–7, during which some 15,000 children lost their lives. In such matters division of administration involves the weakening of the machine. Two separate bodies, even with the best intention, do not accomplish that which would be effected by one body endowed with the powers of both.

In England the difficulty is being met by the constitution of the Health Authority as the Education Authority, and this has in it the basis of an effective machine. The Health Authority has, however, not always been provided with the necessary machinery to effect the object in view, and this machinery must be developed and adapted for the new work which it is required to undertake. Changes are slow, and some mistakes are made, but in the end the true issues are usually seen, and progress in the right direction is made. The guiding principle must be that the administration which is designed to protect the health of the population at "all ages" is that which must be concerned with the health of the child at school age, whether in the school or in the home.

The question may well be asked, To what extent does attendance at school contribute to the number of cases of infectious disease in the population? The information required to answer this question is scanty, but some indication of the extent of this contribution is afforded by a comparison of the number of cases occurring in holiday periods with the number occurring in periods when children are attending school, and in this connection I might cite the figures arrived at by comparing the number of cases of scarlet fever and diphtheria which actually occurred in the month of August during the ten years 1895–1904, with the number of cases of scarlet fever and diphtheria which would have occurred in London in that month had the schools remained open instead of being closed, this latter figure being arrived at by estimating the cases for the month of August from the actual notifications in the two preceding months of June and July and the two succeeding months of September and October. The difference between the actual and the estimated cases is in respect of scarlet fever 3,974, or 27.6 per cent., and in respect of diphtheria 2,002, or 23.3 per cent.

A legitimate criticism of these figures would be that they may be due not to actual decrease in opportunity of infection during the school holidays, but to—(*a*) diminished population in London, owing to the exodus of young persons at the time of the August holiday, or (*b*) the system of notification being less operative during the summer holiday, owing to the children being less under observation than during the period they are attending the schools, or (*c*) to a combination of both circumstances.

On these points I may observe that with regard to (*a*) much the same decrease is observed in the August holiday among the child population of those places in the country to which the London population resorts at the time of the holiday. On turning now to (*b*) it must be admitted that the notified cases of infectious disease in these places would experience somewhat similar diminution if the decrease were due to the cessation during the holiday of observation of children in school.

Concerning this point of criticism I may, however, point out that the decrease of notified cases of infectious disease in children of school age is often followed a week later by decrease of notified cases of infectious disease among children of a younger age than the school age, suggesting very strongly that there has been diminished opportunity for these younger children to acquire infection from other persons, and this finds its most ready explanation in actual decrease of infectious disease among children of school age.

My own view is that there is decrease of infectious disease among children of school age as the result of closure of the schools during the summer holiday, and that the figures given above represent substantially what that decrease has been, or, in other words, the proportion of cases of infectious disease which at that period of the year was due to the opportunities of infection from person to person as the result of aggregation of children in school. In any attempt to estimate the proportion of cases of infectious disease which during the whole year may be due to this circumstance, it is necessary to recollect that in the autumn months both scarlatina and diphtheria show a marked increase of prevalence, and it may be that there is an ability of the disease to spread in school at that time which is greater than its ability at other times. If this be the case, the actual proportions of cases in the whole year due to school attendance would be less than is suggested by the figures given above.

The facts, however, go to support the view that prevalence of disease is maintained by inconspicuous cases, whether mild and unrecognised cases, or by cases of persons who, having no symptoms of their own, are merely "carriers," with an ability to infect susceptible persons.

Hence arise our difficulties in dealing with infectious disease in schools, the difficulty of detecting exceedingly slight cases of disease, the still greater difficulty of detecting "carrier" cases.

Obviously, any child who is suffering from an ailment that raises question of infectious disease should be at once excluded from the school, and inquiry should be made as to the nature of the malady. In this matter the teachers can and do render invaluable service.

(a) Introduction to Discussion at International Congress on School Hygiene. London, July, 1907.

and the extent to which they exercise watchfulness over the children under their charge will often determine whether disease is limited to a single child or whether it spreads to other children. Again, the exclusion of children coming from infected homes is a principle which is generally accepted, although certain modifications in the applications of this principle are possible in practice, owing to differences in the behaviour of the various infectious diseases which commonly affect school children.

In dealing with outbreaks of infectious disease in schools, the question will always arise whether dependence should be placed on the exclusion of particular scholars, or whether the closing of classes or schools should be resorted to. This is a subject which will engage the serious attention of this Section, and it may be hoped that the papers which will be read will contribute to the knowledge required for determining under what circumstances " exclusion " or " closure " should be adopted. Where bacteriology can be employed, as in the case of diphtheria, the first of these methods is largely adopted, and hopes are held out that the complete examination of material from the throats of the children attending an invaded school, and the exclusion of all children harbouring the Klebs Loeffler bacillus may suffice without the more extreme step of closing the class or the school. To determine whether this will prove to be sufficiently effective at all times, at the height of an epidemic, as well as at times of smaller prevalence, further experience is needed. Results which are obtained during the decline of an epidemic cannot always be relied upon as affording sufficient ground for inference that the same method will be equally effective at a time when diphtheria in a community is rapidly increasing in proportion ; but, however this may be, there is no question that ample provision should be made both in respect of bacteriological laboratories and in staff for complete enquiry into the condition of the children attending the invaded school. The more thoroughly this work can be done the greater is the hope that the exclusion of particular scholars will suffice. Other considerations have to be held in view to determine whether the school shall be closed, especially when other diseases are concerned which cannot thus be dealt with. Beyond the question of the extent to which the school is invaded there remains the further question of the proportion of children attending the school who are susceptible to attack. As the result of previous recognised or unrecognised attack, and as a result of natural immunity, there must be a considerable balance of children who are safe from further risk of infection. If we were to judge from the number of cases of scarlet fever which are notified we do not find evidence that any large proportion of London children suffer from this disease. Thus, taking the experience of London during the ten years 1897-1906, we may learn approximately that of children under ten years of age living in 1906 only 63.8 per 1,000 had been attacked ; among those at the other ages being under nine years, 57.5 ; under eight years, 50.4 ; under seven years, 42.2 ; under six years, 33.9 ; under five years, 25.2 ; under four years, 17.2 ; under three years, 10.4 ; under two years 5.2 ; under one year, 1.7 per 1,000. Notified cases, however, provide an incomplete basis for estimating the proportion of children who have passed through an attack of the infectious diseases, and we can in no way assume that the balance represents the number of susceptible children remaining. In some degree the number of modified cases is swollen by cases notified in error, but, on the other hand, not all the cases of recognised infectious diseases are notified, and still more certainly, only a proportion of the actual cases which occur are recognised. Further, it is common experience that only a proportion of the persons exposed to infection are attacked, even when, so far as can be known, they have never before suffered from the malady ; hence nothing but actual experience can show what infectious disease will do if left unchecked in a class or school of children of any particular age. On these points interesting material will be placed before the Section.

In view of the special incidence of infectious disease upon children in the first few years of life, the question of the age at which these children should be required to attend school is a subject well deserving of study, and will be before this Section. In England the age of compulsory attendance is five years, in Germany it is one year later. An examination of the statistics of infectious disease of communities having a different age for attendance should throw some light on this subject. If the age of attendance be deferred, protection from attack of school-derived mealses would obviously not be extended to every child under that age. If older brothers or sisters contracted measles in school, they would bring the disease home to younger brothers and sisters, although these younger brothers and sisters, if they themselves attended school, would have the additional risk of exposure to measles in the school itself. It is, of course, the family of a single child which would derive the most benefit. How would deferred school attendance show itself in the statistics of infectious disease ? It is quite likely it might be manifest in the case of scarlet fever and diphtheria, and but little, if at all, in the case of measles. The subject is well worth inquiry, which, of course, should relate to each of the diseases with which we are concerned, inasmuch as they do not manifest the same degree of infectivity. Unfortunately, it is the usual practice to group for the purposes of publication all cases occurring from five to ten years of age, and here I may make an appeal to those who have the tabulation of these figures that, whether published or not, the number of attacks and the number of deaths should be separated for each year of life so as to be available to determine statistically a question of this sort. However, " the lower age limit of school attendance " will be before us from the pen of an especialy able writer, and the need for the proposal I have made may be better determined after we know the contents of this paper. Under all circumstances we may bear in mind that if the age of attack is deferred it results in a lessening of the fatality of the disease and that, if postponement of age of attendance at school leads to postponement of age of attack, the result will be a saving of child life.

I have made no mention of prophylactic inoculations but I may say that the value of vaccination as a preventive of small-pox needs no mention here. Experience of the use of antitoxic serum as a prophylactic in schools is much more limited, but good results have been claimed for it.

One of the advantages of school attendance is the opportunity which is afforded for dealing with all conditions of health of that part of the population which is of school age, whether they affect life or only cause inconvenience. Hence, the parasitic diseases of the skin, trachoma, &c., are included in our programme. Of these I need say nothing more than to insist on the great advantage to the population which would result from a systematic treatment of all children who suffer from contagious maladies of this sort. There should be no difficulty in the practical eradication from the population of all such conditions if the work is seriously undertaken in connection with the children who are brought under observation in the schools and if the work be followed to the home where the younger children are found. In the same way it may be pointed out how much may be done for the cure of pediculosis. A condition of this sort ought not to be tolerated in a civilised community, and school attendance gives a claim for interference with this condition in the child population.

A BIRD'S-EYE VIEW OF NEURASTHENIA.

By M. MARC., M.D.,

Professor of the Faculty of Medicine, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

If the term neurasthenia had not been distorted from its original meaning, if under this title there were no tendency to describe a definite disease of the nervous system, no term could be more appropriate as applied to certain nervous states.

Unfortunately, and especially in neuropathology, physicians cannot resist the temptation to systematise, to create morbid entities which, once promulgated, are erected into absolute dogmas. Neurasthenia is a curious example of this regrettable tendency of the human intellect.

Formerly authors used to describe under the name nervousness all nervous states not dependent upon lesions of the nerve centres, and manifested by very diverse features, the only characteristic feature whereof was indeed their abnormality. Hysteria, for instance, was a form of nervousness. Some very suggestive contributions, cleverly handled by Beard and, later, by Charcot, rendered it necessary to distinguish between hysteria and neurasthenia, and by artificially grouping the symptoms of nervousness they succeeded in building up two special diseases of the nervous system, two neuroses capable of identification by their respective stigmata. The morbid picture was so admirably drawn that it was universally accepted, and forthwith everybody was on the look-out for neurasthenic subjects, with a large measure of success, for plenty of persons presented the typical stigmata evoked by the interrogative suggestion of the examiner.

Beard, in order to explain how it was that such a striking disease could previously have escaped recognition, admitted that neurasthenia was a new disease caused by the complexity and overstrain of modern society. It is odd to notice that the same explanation has been given of the prevalence of appendicitis, which we learned from the works of Sir Frederick Treves, and of the tabetic arthropathy which was unknown before Charcot called attention thereto.

But observers soon found themselves hampered by the narrow limits assigned by Beard. They were, to begin with, obliged to admit that hysteria, this other "one and indivisible" disease, was sometimes associated with the other neuroses and Charcot conceded the existence of hystero-neurasthenia, just as, since his time, we speak of hystero-epilepsy. The distinguishing features of neurasthenia were so commonplace that they cropped up everywhere. Neurasthenia was for the nervous system what influenza was for the respiratory tract, the disease responsible for everything, which would explain everything. Then specialists took to describing special forms of neurasthenia, and we were treated to dyspeptic neurasthenia, cardiac neurasthenia, syphilitic neurasthenia, gonorrhœal neurasthenia, and so on.

In short, the unduly narrow limits of neurasthenia gave way on all hands, and after having been the fashionable disease, neurasthenia has comparatively fallen into abeyance and is less frequently invoked. Professional opinion has gradually undergone an evolution, and neurasthenia is no longer regarded as a special disease, but rather as an abnormal state of the nervous system, characterised more particularly by inadequate reactions and a tendency to depression. Like the hypochondriacs of former times neurasthenics are usually depressed, tiresome and tired, complaining of everything, and more alive than their normal fellows to all kinds of disagreeable sensations and impressions, so much so as to make mountains out of mole-hills. The loss of will-power renders them unable to resist these auto-suggestions or to throw them off; in short, their nervous system is inadequate, lacks spring, and is asthenic. As suggested above, no term better describes their plight than the word neurasthenia, provided no very exact meaning be attached thereto.

Neurasthenic patients only present one feature in common, viz., nervous asthenia, but no one symptom or stigma is always present. No two patients differ more than two neurasthenics, and nothing equals the variability in course and duration of the neurasthenic condition.

The gravity of neurasthenia depends upon its cause, and we may divide these patients into two principal classes:

(1) Constitutional neurasthenics who have been so from their infancy and will continue so till they die. They have inherited a sort of functional malformation of the nervous system due to parental strains, they, are usually the offspring of neurasthenic, epileptic alcoholic or morphinomaniacal parents. Everything tends to aggravate the neurasthenic state in these subjects, and no sooner is one manifestation cured than another takes its place.

(2) Accidental neurasthenics. A violent moral or physical shock, a painful emotion, a traumatism, an attack of disease, an intoxication, or mere overwork may determine neurasthenia in any individual previously in good health. These, however, do not long remain in a state of neurasthenia, but soon recover under treatment. The nervous system, depressed for the time being, reasserts itself under the influence of rest, hygiene, etc., or after the disappearance of the disease to which it was secondary.

This is the origin of the neurasthenia that attacks young people who have worked too hard for examinations, or business men whose occupations have been too much for them, or persons who have been smitten in their affections or have been bereaved, or who have been subjected to intense disappointment or who have been in a railway accident. The same remark applies to the victim of poisoning—tobacco, lead, syphilis, tuberculosis, dyspepsia, etc. The depression is fully explained by the cause, though in some instances the result may be altogether out of proportion to the apparent cause and may, moreover, have disagreeably persistent effects. This, however, is only the case in persons predisposed thereto, so that the neurasthenia in such persons is more constitutional than accidental, and the cure is consequently relative and not absolute.

Neurasthenia hardly lends itself to a general symptomatic description. Each individual has a neurasthenia of his own. The common character of impotence, inadequacy and depression is present in all, but the nervous disturbance bears on this or that part of the body, according to the local predisposition or lessened resistence. Every morbid symptom, every painful sensation, is enhanced and rendered more persistent by the neurasthenic state.

In neurasthenia we only get subjective symptoms which do not admit of verification. The disease consists in the patient being acutely conscious of a number of minor ills to which the healthy individual would not condescend to pay attention. When we examine a neurasthenic subject everything lies in his narrative, nothing abnormal can be detected, yet he takes immense pains not to overlook the most insignificant detail. One patient insists on his headache, his neuralgia or his tremors which no one else can detect, while another emphasises his constipation and his multiple abdominal sensations. They will not willingly spare the physician a single detail, we have to take cognisance of all the analyses of urine and, if of some standing, the patient will produce a sample of urine ready for examination along with a sample of fæcal matter.

As a general rule neurasthenics complain of persistent headache which sets in on rising, compresses the forehead and skull like a helmet, spreads down the occiput and neck, is exasperated by work, noise and light, is accompanied by giddiness, noises in the ears, disturbances of vision and, in some instances, by hyperæsthesia of the scalp. He constantly feels weary and rest does not bring any relief. They feel so limp that they would prefer not to get up or walk or go out. They get attacks of fatigue quite suddenly, following an emotion or a worry or even without any obvious cause. They complain of aching in the back, or dorsal pain. The rachialgia, which is characterised by a sensation of pressure or compression, is generally increased by pressure on the spinous processes; the skin may even be hyperæsthetic, and they declare themselves unable to bear the weight of the clothes. The back pain is most marked at the lower part of the spinal column and the "sacral patch" is one of the classical signs.

The digestive disturbances have been specially investigated by Bouveret and Mathieu. Usually the condition is one of gastro-intestinal atony, the appetite is capricious and poor, the patient feels hungry and cannot resist the sensation without feeling faint, so that he eats at all times. At table, however, after the first few mouthfuls he has had enough. He feels better after a meal, but this does not last long for he soon complains of a feeling of weight in the epigastrium, of swelling of the stomach, of eructations, flatulence and palpitation, and he feels drowsy. Constipation and muco-membranous entero-colitis often accompany this morbid condition. The state of the gastric juice is variable, sometimes the secretion is insufficient and poor in hydrochloric acid, in others, on the contrary, there is hyper acidity.

The gastric troubles are most pronounced in the grave cases in which the patient becomes emaciated and loses strength, and we are tempted to think of cancer.

Insomnia is of frequent occurrence. The patients are a long time in getting to sleep and awaken in a mental state of excitability or even anxiety. They get to sleep again with difficulty and often have disagreeable dreams.

The principal psychical trouble consists in a diminution of the personality with enfeeblement of the mental faculties, inability to concentrate the attention, and a tendency to sad thoughts. The emotions are not under control, and the memory is impaired. The will-power is almost completely lost, so that the patient is incapable of arriving at the most trifling decision, even in regard to his ordinary occupations or habits of life. Every act is a burden to him, he hides himself from everybody and everything. Unable as he is to fix his attention he cannot read or work, and his conversation is incoherent. He often experiences unnecessary apprehensions, he thinks he is suffering from some dreadful disease, and it is very difficult to get these ideas out of his head.

In addition to these general symptoms we get certain secondary manifestations, such as continuous or intermittent giddiness. This is relieved by rest in bed and by taking food, but not always. It may be accompanied by a dazed feeling with disturbances of vision and noises in the ears, in fact, the syndrome of Menière. The patient complains of cramps, of fibrillary contractions of the muscles, twitching of the eyelids and trembling of the hands. The hyperæthesia may be limited to some part of the body, but is most frequently localised in the scalp or over the sacrum. Such patients may complain of every conceivable painful sensation. Sight might appear to be disturbed, the eye quickly tires, the image becomes blurred and the patient experiences painful distension of the globes as soon as he attempts continuous work, yet ophthalmoscopic examination of the eyes shows them to be normal.

The genital organs are frequently incriminated, such patients suffer from nocturnal emissions which disturb and alarm them, and they are devoured by the terror of becoming impotent.

Attacks of palpitation supervene under the influence of some trifling emotion or fatigue, the patient thinks he has heart disease, and is dissuaded from that belief with the greatest difficulty. His apprehensions are sometimes intensified by persistent tachycardia, irregularities of the pulse or attacks of pseudo-angina. Urinary symptoms may be present. There may be pollakiuria or urethral smarting. Phosphaturia has often been mentioned among the symptoms of neurasthenia, but that is a mere error of diagnosis. The presence of a phosphatic deposit in the chamber is not due to excessive elimination but to precipitation consequent upon the reaction of the urine or to an insufficiency of the aqueous vehicle. Demineralisation and leakage of phosphates have never really been met with except in presence of emaciation.

The diagnosis is easy; too easy indeed. The physician must be careful not to label as neurasthenic disturbances due to disease of the heart, stomach or lungs. We must never proceed on the strength of a mere statement, but must examine the patient thoroughly in order to make sure that the apparent neurasthenia does not mask some organic trouble. Certain persistent headaches, with loss of memory, change of temper and mental depression may usher in general paralysis, but if these symptoms are associated with inequality of the pupils and impaired reflexes lumbar puncture will enable us to make the distinction. Headache and vertigo may be due to cerebral tumour or to syphilis, as can be ascertained by careful examination and close observation of the exact symptoms. Pain in the limbs with persistent weakness and dulled reflexes may be indicative of tabes, but the Argyll Robertson pupil, the abolition of the reflexes and Romberg's sign will put us on the right track.

The diagnosis may sometimes be rendered difficult by the fact that the symptoms of the organic affection are at times very ill-defined and that such affections often give rise to neurasthenic manifestations: in short, we must learn to detect the organic lesions behind the neurasthenic mask.

We must likewise display a judicious scepticism in respect of all elderly *soi disant* neurasthenics who complain of inability to work, dyspeptic troubles, vertigo, headache, palpitation and feeling of numbness, because the examination of the urine, the heart and the large vessels will in some cases enable us to identify Bright's disease or arterio-sclerosis.

Lastly, we must be careful not to diagnose as cases of neurasthenia certain states characterised by languor with anæmia and loss of appetite and strength supervening in young subjects, for these signs may be merely the manifestations of latent tuberculosis.

In short, we must not be in a hurry to formulate a diagnosis of neurasthenia; this should always be very guarded indeed; it should be considered rather as a refuge for the destitute, that is to say, merely the result of our inability to discover any organic lesion capable of determining neurasthenic symptoms and even in constitutional neurasthenics we must always make careful research for affections likely to give rise to the neurosis.

Neurasthenia is always very difficult to cure when it is not purely accidental. The first indication in the treatment is to attack the underlying affection: treat the syphilis, stop the overwork, calm the emotions and so on; that is the real way to overcome certain types of neurasthenia.

Hygienic measures constitute the basis of the treatment. The patients should avoid undue fatigue, they should be incited to take regular, graduated, physical exercise in the open air, and in most instances a period of rest treatment at a certain altitude is indicated. Hydrotherapy in the form of douches and baths is of service, hot for excitable subjects, cold for the depressed. Wet packs, rubbing with alcohol and cold salt water baths, general massage and local massage in certain painful manifestations, statistical or faradic electricity, are all valuable in their way.

Medicinal treatment plays a secondary part, but nervous sedatives and soporifics are useful to subdue the nervous excitement, ensure sleep and allow of rest. Stimulants, such as strychnine, arsenic and phosphates are useful adjuvants, whether they act as tonics or by suggestion.

Every prescription must be accompanied by cheerful encouragement, for the moral influence of the physician is of the highest importance, though truly it entails much patience, tact and persuasion.

In obstinate cases the treatment of neurasthenia cannot be carried out at home; the patient must be withdrawn from his usual environment in order to disassociate him from his preoccupations, and he must be isolated in a nursing home or he may be sent to a health resort in the mountains with rest, massage, electricity and a special dietary. These are the main features of the Weir Mitchell treatment now adopted by all specialists in this department.

The Committee of the National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis are about to open the second half of their main building at Benenden, Kent, which will accommodate 68 patients.

THE OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL.

Chlorosis and Early Tuberculosis.

By Leonard Williams, M.D., M.R.C.P.,
Assistant Physician to the Hospital; Physician to the French Hospital in London.

This girl, whose age is 17, has been to see us three times. On the first occasion she was obviously and grossly anæmic, with that peculiar tinge about the face which has given rise to the name of "the green sickness." We examined her heart, and found that it was substantially normal, there was no albumen in her urine, and we were therefore justified in provisionally labelling her case one of chlorosis. There was, of course, a history of scanty and irregular menstruation. That is so common in these cases that it may almost be regarded as a symptom. In this case the scantiness had proceeded to the point of complete suppression for the last two months. Another almost invariable accompaniment of the condition is constipation, and another very common association is carious teeth. This girl's teeth were not carious, but she was constipated. She was given a medicine containing ferri ammon. cit., 15 grs.; liq. arsenicalis, 3 minims; tinc. nucis vom., 4 minims; and water to half an ounce, three times a day, together with an aloes pill to be taken in the course of the afternoon. Aloes is always the best form of aperient to exhibit in these cases, because in some obscure way it seems to heighten the effect of the iron.

On the occasion of her second visit she was improved, but not markedly so. The constipation was better, but her anæmia, though less, was still very pronounced. The dose of the iron was therefore increased to 20 grs., and that of the arsenic to 5 minims.

She comes to-day still slightly improved, but the result is disappointing. Iron and arsenic in cases of pure chlorosis may be regarded as specific, and if they do not cure a case of this kind, then either we have combined our drugs badly, or there is something else the matter with the patient.

In this girl's history there is one factor of rather sinister significance. I have said that in chlorosis menstruation is liable to be irregular and scanty, but it is not very often totally suppressed. Total suppression of the menses has been described as one of the earliest signs of tuberculosis, and I need hardly remind you of Trousseau's saying that an anæmia which resists iron is probably due to tubercle. These two factors being present in this case were sufficient to arouse the suspicion that the "something" which was preventing this girl from reacting to iron was a tuberculous invasion. We therefore searched for other signs.

A very early sign of tuberculosis is tachycardia, which, as I have often previously explained, is due to vaso-dilation, which may be regarded as one of the physiological effects of the tuberculous toxin. Now this girl's pulse is no less than 120 per minute in the upright position. It falls to 90 when she is recumbent—that means that the vessels are unduly dilated. We have therefore three facts to go upon—a chlorosis which resists iron, suppressed menstruation, and tachycardia. These three in themselves, though not serious, are distinctly disquieting.

The girl, you will observe, has very little pigment in her hair. That in itself is sufficient to excite a certain amount of suspicion, and some of you may have noticed, when I was examining her chest, that she had a line of fine down passing from the hair of her head to between the scapulæ behind. That, according to some people, is another sign to be viewed with apprehension.

The examination of the chest revealed nothing very definite. There were the differences between the right and left apices which are so often found in perfectly normal people—that is to say, the right side was rather less resonant than the left, and the voice conduction was rather better. The breathing on the right side did, however, present an abnormality which it is difficult to describe, but which has been called "harsh breathing." It is not that such breathing is necessarily high-pitched, or that it has any of the characters of what we call bronchial breathing, but it is harsh. It offends the ear, so to speak, and is in very marked contrast with the weak breathing which is to be found on the other side. Though I listened carefully I could not find anything in the nature of cog-wheel breathing. The examination of the chest, therefore, has given us no very strong confirmatory evidence.

How are we going to set our suspicions at rest? Well, if we take the girl into the wards and record her evening temperatures, we shall probably find something very definite to go upon. We shall probably find, that is, that she has a slight evening rise—a rise not sufficient to cause her any discomfort, but one of which the thermometer will tell us in unmistakable terms. The chart may be expected to show us that, though her temperature is possibly sub-normal in the morning, it rises to a degree, or a degree and a half, above normal in the evening. This is a very important point, and in suspicious cases it is one which should always be carefully investigated.

Another confirmatory sign is to be found in the ulnar reflex. When we made this girl stand at the table with her fore-arms resting thereon, and the arms flexed at the elbow, you saw that when I drew a pin smartly along the ulnar surface from elbow to wrist, there ensued a wrinkling of the hypo-thenar eminence, due to a contraction of the abductor minimi digiti, and that this phenomenon was present on both sides. Now this ulnar reflex is not pathognomonic of tuberculosis, but its presence affords very strong confirmatory evidence of suspicions otherwise aroused. Like so many other of these reflexes, its absence means nothing. It is often absent in advanced cases of phthisis, especially in men who have worked with their coarser muscles rather than with their finer. It is more easily elicited in women on account of the better development of the abductor minimi digiti which constant use of the finer muscles of the hand naturally gives rise to. This ulnar reflex is occasionally present in some other conditions, but it is on the whole very rare except in tuberculosis. In a person of the age of this patient its presence affords evidence which it is very difficult to gainsay.

Further confirmation could, of course, be obtained by examining the sputum for tubercle bacilli, but inasmuch as the patient has no cough, it would be very difficult to obtain sputa coming from the lungs themselves. Any sputa that she produced would probably be salivary only. Nevertheless it is our duty to see if such an examination will help us.

Another laboratory method which is now deservedly attracting a very considerable amount of attention is the estimation of the opsonic index. That, fortunately, is a comparatively easy matter, and before she leaves the hospital this girl will go to the laboratory for the purpose of allowing us to ascertain what her opsonic index is.

You may be inclined to say that the foregoing constitute a very flimsy basis whereon to construct a diagnosis of so grave a condition as pulmonary tuberculosis; but the time has now gone by when, before commencing treatment, we used to wait until there was an involvement of the pulmonary area so definite that it was accessible to ordinary percussion and auscultation. If we wait for the classical physical signs before commencing treatment, then we have waited too long. Phthisis is, no doubt, under entirely favourable circumstances, a very curable disease, but the condition precedent to its curability is its detection in the very earliest stages.

It is now our business, therefore, to look for signs of tuberculous invasion which were formerly relegated to positions of minor importance. The laboratory methods to which I have just referred happily afford us an amount of assistance which in the large majority of cases reduce suspicion to a certainty. This patient I believe to be suffering from commencing phthisis. Her opsonic index, when we know it, will set the matter at rest, and it is even possible that the examination of the sputum may also confirm the suspicions which her general condition has aroused.

Now, if we are to cure this girl, how are we to set about it? If I were to ask this question of you individually, each one would certainly say "send her to a sanatorium." Unfortunately it is not very easy to get girls from the out-patient room of the hospitals into sanatoria; and even when we succeed we are not able to select the sanatorium into which they shall go. Assuming that the methods of treatment are substantially the same in all sanatoria—and I think that nowadays such is a reasonable assumption—there is one factor in the situation which is of the very highest importance, which unfortunately we are not in any way able to control. This factor is the climate of the place in which the sanatorium is situated. There are, as you know, bracing and sedative climates, and in private practice the success or otherwise of a sojourn in a sanatorium may depend largely upon the suitability of the climate in which the selected institution is situated. The circumstances which lead us to select one climate rather than another in an individual case are so complicated that I cannot even outline them here. I may, however, say that young people, about the age of our present patient, do best in a climate which is neither too sedative nor too bracing, and that the older people grow the more sedative should be the climate to which they are advised. There is a certain type of lymphatic tuberculous person, generally young, who does so surprisingly well in bracing climates, such as that of Margate, that one is apt to think there must be something specific against tuberculosis in climates of that type. Against this pitfall I wish you particularly to be on your guard. The results of Margate in suitable cases approach the miraculous, but in unsuitable cases such a climate will frequently send a patient downhill with a rapidity which is truly alarming.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Amputation of Thigh for Senile Gangrene. Lumbar Analgesia.—Mr. Edred Corner operated on a woman, æt. about 76, who had been admitted with senile gangrene of the right leg extending nearly up to the knee. There was no pulsation in the right anterior and posterior tibial arteries. There was pulsation of the same arteries of the left leg. She had been ill for a fortnight. Her heart and arteries were extensively diseased; in fact, so much so that it would be unwise, Mr. Corner said, to give her a general anæsthetic. It was therefore decided to perform an amputation at the upper third of the thigh, stovain being injected through a lumbar puncture. In this case there was some slight difficulty in performing lumbar puncture because the patient had some osteoarthritis of her spinal joints which caused rigidity of the spine in consequence of which it was impossible to flex the spine and separate the laminæ of the vertebræ. Anæsthesia came on rapidly after the injection and extended nearly up to the nipple line. The amputation was carried out with skin flaps and the patient experienced no discomfort whatever. Both femoral artery and vein were thrombosed at the point of section, but though the main vessels did not bleed, the branches from above bled copiously, therefore showing that there was plenty of blood supply for the flaps. Anterior and posterior skin flaps were cut and reflected then the muscles were divided circularly and retracted, and the bone sawn through a little higher. The steps of the operation were carried out quickly and quietly, the patient's ears having been closed with wool just before the bone was sawn through. The vessels were ligatured and the flaps united without drainage. During the operation the patient conversed freely with the anæsthetist, Dr. Mennell, and declined the offer of a cup of tea, as she said she was not thirsty. Mr. Corner said this case illustrated the uses and advantages of lumbar anæsthesia; it was a method, he thought, which could never be used for general purposes on account of the patient remaining conscious, the headache, pain, and sickness it sometimes causes, and the slight risks which it entailed, such as the occurrence of meningitis; moreover, he had seen it produce severe symptoms, incessant vomiting, and feeble pulse during the period of anæsthesia; in addition, on rare occasions it has failed to produce any anæsthesia, as, for example, in a young man about to undergo an operation for varicocele, when the discoverer of stovain, Professor Fournier, of Paris, was present; but in cases such as the present in which it was undesirable to administer a general anæsthetic, the use of lumbar anæsthesia was invaluable. As a general rule, it produces an anæsthesia which lasts about three-quarters of an hour, and extends up to the ninth or tenth dorsal nerve, so that any operations on the legs or the lower part of the abdomen can be done painlessly. The method of producing anæsthesia by spinal injections, he remarked, has been used in the cervical region to enable operations to be performed on the neck, chest and arms, but its use in this region has never been popular on account of the greater difficulty and danger of the operation.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Sept. 15th, 1907.

Atrophy of the Tongue.

Lingual atrophy is either total or partial; the former is rare but can be observed in glosso-labio-laryngeal paralysis of bulbar, cerebral, or basilary origin.

The development of the affection is slow and progressive, and commences by paralysis of the tongue, followed gradually by that of the lips, larynx, and pharynx, producing difficulties in mastication, deglutition, and phonation.

The patient salivates incessantly, becomes emaciated, and succumbs after several months.

Where both lingual nerves are paralysed simultaneously, the tongue is atrophied, although the lips and face may preserve their normal mobility. Total atrophy has also been observed in progressive muscular atrophy.

Such are the usual causes of total atrophy of the tongue, which, however, is a very rare affection.

On the other hand, hemi-atrophy is more frequent, and has been observed in cerebral affections, encephalitis, hæmorrhages, softening, &c. But the origin of this curious lesion is found particularly in affection of the bulb. The lesion can affect the nuclei of the lingual nerve from meningitis or pachymeningitis, producing compression and atrophy of centres of origin. According to Ballet, hemi-atrophy of the tongue is seen sometimes at the commencement of ataxia and constitutes an excellent element of diagnosis.

In syringo-myelia, partial atrophy coincides with paralysis of the velum palatum as in all bulb lesions; the same is observed in the course of sclerodermia or tropho-neurosis, and especially observed in the female sex.

Lesions of the lingual nerve, due to traumatism or neuritis, can produce partial atrophy.

Generally, the patients are unaware of the deformity, which is discovered frequently by chance. But, nevertheless it, when recognised, puts us on the track of certain nervous affections, as ataxia, for instance—hence its importance.

Cervical Adenitis.

Dr. Calot, of Berck-sur-Mer, the well-known authority on diseases of children, recommends the following treatment for cases of cervical adenitis, which, when operated upon without precaution or left to themselves, leave behind very unsightly scars.

If the abscess is very ripe, the following should be injected—

Creosote, 4 m.
Iodoform, x. grs.
Olive oil, 1 dr.

If the abscess is not ripe—

Camphorated naphtol, xv. gr.
Glycerine, 1 dr.

The amount injected should correspond with half the cavity of the abscess, so as not to distend the walls. The injections should be made every four or five days, and seven or eight given in all.

If the abscess when first seen is ready to open, a small puncture should be made beneath the tegument, but without injection, and repeated if necessary several days consecutively until the skin has recovered its integrity; then the injections might be given. After the eighth injection, compression is made so as to bring the sides together.

In case of non-suppurating ganglions, general treatment should be prescribed, and the patient counselled to have patience. Warm compresses of salt water might be applied several times a day as a resolvent, while antisepsy of the nasal fossæ, the mouth, and the teeth so as to disinfect all the tributary territories of the ganglions, should be practised with care and perseverance. The patient might also be sent to the country, to the sea, or to the saline waters of Biarritz, Bex, &c.

In very many instances, improvement takes place, and a total cure follows at the end of a few months.

If softening of the ganglion sets in a favourable moment will be awaited to operate as above.

It sometimes happens that the ganglions remain torpid; they maintain their hardness and volume. In such cases, says Dr. Calot, a modifying liquid should be injected into the ganglion. Five or six drops of camphorated naphtol (pure) injected every three days, favours the absorption of the gland, which, at first swells, increases in volume, and then gradually subsides and disappears finally at the end of four or six months. The number of injections to be given are seven or eight, with three days' interval between each injection.

If from six to twenty drops of camphorated naphtol were injected every day, suppuration would set in, and then the usual treatment could be applied.

It is preferable, in general, to provoke the suppuration as a cure is more quickly obtained.

Fortunately, adds Dr. Calot, a cicatrix is much more easily avoided than effaced. It can be almost always avoided by the treatment he recommends. It is true, this treatment requires perseverance and a much longer time than a rapid and brilliant extirpation, but this last leaves an indelible mark, while his treatment cures without a trace.

WARTS.

Apply a thin layer of black soft soap at night to the hands, and dust them with talc or any other absorbent powder in the day time; or,

Sulphur, 5 dr.
Glycerine, 2 oz.
Acetic acid (diluted), 2 dr.

Applied the same way as the soap; or

Salicylic acid }
Lactic acid } ā ā xxx. gr.
Resorcin, }
Collodion, 4 dr.

Touch the warts by means of a brush or the cork morning and evening.

Internal treatment acts on the imagination of the patient and for that reason should not be omitted.

Calcined magnesia, xv. grs. For one wafer to be taken daily; or

Tincture of thuja occidentalis, 4 drs.

Twenty drops three times a day.

WHOOPING COUGH.

Ichthyol, ½ dr.
Syrup, 4 oz.
Peppermint, *q.s.*

Two teaspoonsful daily.

Under the influence of this simple remedy the attacks diminish rapidly and at the end of two or three weeks the child is cured.

Nasal antisepsy by instillations of liquid vaseline and menthol and also intestinal antisepsy by castor oil administered frequently, constitute a good adjunct treatment.

GERMANY.*

Berlin, Sept. 15th, 1907.

AT the Medizinische Gesellschaft Hr. Bickell communicated a note on

THE INFLUENCE OF METALS ON GASTRIC SECRETION.

He said that all metals that gave off hydrogen in dilute solutions of hydrochloric acid stimulated the mucous membrane of the stomach to secretion; for example, iron, manganese, aluminium. Tin, bismuth, silver, and gold were therefore weak or only slightly active. "Escaline" (metallic aluminium with glycerine) had a powerful action on the gastric secretion, and for this reason it was contra-indicated in cases of ulcer of the stomach, although it was recommended for that purpose. "Escaline" had no hæmostatic properties as experiments on animals had shown. It was decomposed in the presence of human blood. (This reaction was demonstrated).

Hr. Rumpel showed two patients with

CYSTIC DISEASE OF BONES.

1. The patient had been ill for two years. The disease began with pain in the right ankle, which resisted all the various kinds of treatment made use of. The talus was puffed, whilst the joint of the foot was free. A diagnosis was made of new growth in the talus. Röntgen illumination showed a cystic tumour. The operation undertaken for removing the talus confirmed the diagnosis. Microscopic examination revealed a round-celled sarcoma. The patient was now walking quite well.

2. A female with cystic tumour of the femur. The disease began a year and a half ago with pain in the left hip joint. All treatment was in vain. The patient came to the surgical clinic in the beginning of April. Examination showed that the hip joint was free, the disease being situated in the upper part of the femur, which was swollen and very painful. One had the sensation, on pressure, as if a "'pit" was made in the part. Röntgen illumination showed a solitary bone cyst. At the operation a cyst the size of an hen's egg was found in the upper part of the femur, this was cleared out, and no remnants of tumour were left in the cyst walls. The soft parts were united by suture, and healing took place by first intention.

Hr. Senator showed a case of

"MIKULICZ'S DISEASE."

The patient was a girl, æt. 6, her face was swollen and of a yellow colour. All the glands of the face were swollen and indurated—the lachrymal gland as well. There was also hard swelling of the eyelids, and slight exophthalmos from swelling of the retrobulbar tissues. The case was one of Mikulicz's disease. Moreover, all the lymph glands of the body were greatly swollen. Examination of the blood showed lymphatic leucæmia. To this collection of symptoms was superadded swelling of the periosteum of the flat bones of the skull, especially of the frontal bone; the ethmoid bones also appeared to be affected—one as chloroma or chlorolymphoma or chloromyeloma. There was here, therefore, a triad of rare diseases. The speaker was reminded of a case in which his views did not agree with those of Heubner; he was of opinion, however, that the autopsy showed that his view, that the case was a chloroma, was correct. Two other cases were then shown, one a case of acromegaly, with two rare complications—strabismus convergens and enlargement of the larynx; and the second a case of fibroneuromata.

Hr. Heubner observed in regard to Senator's case, that it was not a chloroma, but a lymphoma of the thymus with leucæmic new growth. At the autopsy there was nothing but leucæmic swelling on the periosteum, and there was no green colouration.

Hr. Marcuse said that he had shown a case of Mikulicz's disease before the Society two years ago, and he would like to report its further course. There was swelling of all the glands and extension of the cardiac dulness. Then great œdema came on, and death took place with ascites and cardiac weakness. The autopsy showed no leucæmia, and only immaterial changes were found in the blood. All the lymph glands, especially the bronchial, were enlarged, some to the size of the fist. According to this the case was one of pseudoleucæmia.

Hr. Senator reiterated that by Mikulicz's disease was understood enlargement of the salivary and lachrymal glands, and there were round-celled growths in the glands. The grey colouration of chloroma was "akzidentell," and was not present in leucæmia.

At the Medizinische Gesellschaft Hr. C. S. Engel gave an address on

REVERSION IN EMBRYONAL BLOOD FORMATION AND THE ORIGIN OF MALIGNANT TUMOURS.

He sketched briefly the development of blood in the human embryo, and concluded with saying that the marrow of bones was the place where the red blood corpuscle was formed, and where it remained all through life, with this distinction that youthful bone marrow was red, whilst that of adults was yellow. The red blood corpuscle also differed in their different stages; first, the only slightly differentiated macrocyst; later, the highly differentiated erythrocyst of the adult.

Regeneration of the blood might take place normoblastically and megaloblastically. The latter process was a reversion in the embryonic condition, with which an end-differentiation of the cell was associated—an atavistic process.

The end-differentiated cells could now develop without limit, without again taking on a distinct character, or they might again assume their specific character.

The same thing happened in malignant tumours, where an end-differentiation of the cells preceded the unlimited development.

He then discussed the question why did not the cells of the embryo grow into the maternal uterus, destroy this like a malignant tumour, and with it the maternal organism; he traced the parallels and enumerated the protective appliances of the maternal organism, and held it here to be not impossible that further inquiry should yield important disclosures for the successful treatment of malignant growths.

AUSTRIA.

Vienna, Sept. 15th, 1907.

STATIONARY PARALYSIS.

AT the Psychiatry Meeting, Rocke raised the question of Stationary Paralysis. Was there such—And was it curable? Under this term a nerve disease was recognised, which went on for years without much change to the onlooker; indeed, some question if paralysis exists. If any one takes the trouble to enquire at a mental institution he will often meet with a history like the following:—A patient is received with paralysis, which may go on for four or five years with very little change, but the patient suddenly dies. The *post-mortem* reveals no cause of paralysis, but on the other hand, the brain will indicate the presence of the syphilitic virus, arteriosclerosis of the cerebral vessels with signs of alcoholic degeneration and dementia præcox. Such cases only teach us how difficult it is to diagnose, and at the same time warn us in the management of large institutions to be careful of sudden deaths.

Alyheimer related the history of a similar case with supposed stationary paralysis. The patient was 32 years of age, and died suddenly. The microscope revealed a syphilitic condition, which undoubtedly caused the paralysis, which could not in the real sense of the word be "stationary."

Kraepelin thought such cases of paralysis were only transitory conditions in the progress of other diseases, and should be carefully observed; but with the serum and cerebro-spinal fluid tests the differential diagnosis and treatment should not be so difficult.

MENTAL MORAL WEAKNESS.

Gudden drew attention to the essential difference of opinion on this subject. Lombroso was convinced that property of the brain was the natural sequence of the mental organ returning to its original level as found in the savage, which is only translation of the animal disposition. On the other hand, Naecke opposes this view as impossible that such a disposition can be transferred from the animal to the human being, and attributes the condition to disease.

Forel has preached for years that the law of evolution is as true of the intellect as it is of the body.

Wasman teaches that a gulf between the animal and human intelligence exists which we cannot exactly fill in. We recognise the one side by intellect, the other by instinct. We may acknowledge the phylogenetic development of the human psyche from the lower animal, and the psyche of the cultured man from the savage; but the question still remains: Is this mental moral weakness similar in quality and character to the savage? Take the negro race of America. It is now established beyond doubt that we are not able by culture and education to raise the black race above that mental plane. Cases are reported of success in this direction, but these are only white-washing—the black never changes in nature.

Nothing will raise them to the higher ethics of self sacrifice, gratitude or truth; even repentance in the negro is unknown, or when it does appear, it is only hypocrisy. The capacity for learning is there, but the power of thinking in the abstract or reasoning from premises with a correct judgment are lamentably absent. We cannot compare the diseased brain of the white man with the healthy organ of the negro; there is no disturbance in the latter, no vision, fancies or imaginings that we have in the diseased brain. The brain of the negro was not first diseased then become sound, and no morbid process had ever entered into its composition—it was an inhibited virgin brain and would remain so by atavism. More importance must be placed on the race than the size of the brain, its coverings, central ganglia, and its peripheral connections.

Experience teaches that punishment by imprisonment or fines has no effect as a deterrent on the negro, but enforced work has some influence.

CONCURRENT ANTAGONISTIC BODIES.

Bresina has been experimenting with animals in the laboratory, and comes to the following conclusion—The animal treated with different blood or erythrocites forms a power of antagonism against all in a greater ratio than the control animal with only one sort of blood, or, in other words, a reciprocal limitation of the antigene is absent. The presence of this antagonistic body in the former does not prevent the formation of other new bodies. The presence or absence of a normal hæmolysin in a serum does not therefore prevent the formation of an immune hæmolysin.

The injection of one sort of blood into a guinea-pig increases the lytic power of other sorts of blood that may follow. We have therefore not only agglutinating bodies formed, but also hæmolytic antagonists and antigenes at the same time, the concurrence of the antagonistic bodies playing no active part whatever. Should prophylactic innoculation be required, one or more make little difference in the result.

SPONTANEOUS BIGEMINA.

Vanysek, at his clinic, exhibited a young man, æt. 28, who when 24 developed sexual neurasthenia, followed by this inversion of rhythm of the heart's action, coming under the generic term of "Allorhythmia," which includes bigemina and arhythmia, the former inverting the beats, the latter an irregularity of movement. Since his illness paroxysms of this bigemina come on with a painful burning sensation over the cardiac region with ice-cold extremities, which he considered was produced by an extra-systole movement which Hering termed an "unabridged bigemina." There was no organic change or other morbid condition present to account for the disorder. There were chronic contractions of the sphincter iridis, making it difficult to examine the fundus exalted vaso motor reflex, isolated bending of the phalanges of the third fingers, with prominent spasms of the platysma myoides present. A strange feature of this case was that the patient could now spontaneously call forth these phenomena and check them at will by different movements, positions, or holding the breath.

Cerebro-Spinal Therapeutics.

Radman has been experimenting with animals on this disputed question of injecting or inoculating under the skin against the original idea of injecting into the dural sac. With cultures of the epidemic cerebro-spinal virus he was unable to produce the disease in animals but when injected into the dura sac the disease was virulent. He therefore concludes that cutaneous or subcutaneous tissue is unsuitable or adverse to the growth of the meningeal cocci and therefore no local or constitutional effects would result from vaccination. Injecting the fluid drawn from the same animal was equally worthless as far as cure was concerned, as it had no effect in alleviating any of the symptoms.

HUNGARY.

Budapest, Sept. 15th, 1907.

At the recent meeting of the Budapest Inter-hospital Association, Dr. Schmidt read an interesting paper on the

Value of Tuberculin Reaction.

He tried to prove that the tuberculin reaction is not infallible in the diagnosis of tuberculosis. His technique is as follows: After absence of fever has been assured, for several days by four hourly measurements, one milligramme of tuberculin in fresh solution is injected, then, after four to five days, five times this amount. In eight cases with positive reaction, tuberculosis was found at autopsy in only five, in three carcinomata of œsophagus and stomach were the sole lesions. In one there was no reaction, yet evident tuberculosis. Despite such small doses and great care in injecting, serious accidents may occur and a latent process may suddenly become active and even lead to a rapidly fatal issue. This happened to Dr. Schmidt in three cases—one of leprosy, combined with tuberculosis, one of incipient apical tuberculosis, and one of affection of the serous membranes. A source of error is to be found in hysterical patients, they sometimes: react after tuberculin injections and even after injections of plain water.

Dr. Feleki spoke of a case of

Henoch's Purpura.

He referred to a patient who had been admitted to the surgical side of the hospital with pain, tenderness and a leucosytosis. She was prepared for operation, with the idea that there was some acute abdominal trouble, but a bilateral purpura was discovered accidentally, a diagnosis of Henoch's purpura made, no operation done, and patient recovered. He referred to another case of his own, in which there was recurrent abdominal pain closely resembling attacks of gall-stone or kidney colic. The appearance of a marked erythema, however, made it clear that the case was one of a visceral crisis accompanying a skin lesion. He said that he had also seen the condition after the administration of the anti-toxin of diphtheria. In this patient a violent erythematous urticaria appeared over the whole body eight days after treatment. With it there was œdema in both eyelids, a slight arthritis. The symptoms promptly disappeared.

Dr. Barta read a paper on

Immediate Repair of Laceration of the Perineum.

He pointed out the importance of closing up even small tears of the perineum, so as not to leave raw surfaces for septic absorption. It was important to close large tears so as to retain the function of the pelvic muscles. The best time to put in these stitches was just before the head pressed on the perineum, while the patient was næsthetised and before the parts had lost their relative positions. With the left finger in the vagina, and the thumb in the rectum, a large perineum needle on a handle was passed just under the vagina, threaded with silkworm gut; the two or three stitches hung loosely in a Pean forceps, until the placenta had been delivered, when they were quickly tied, bringing the parts exactly together as they were before the tear.

Dr. Révész related his experiences regarding

Pulmonary Embolism.

This condition and its evil associate, femoral thrombosis, are as inexplicable as they are to be dreaded. Neither has any bearing on wound infection, in fact, it is well known that each is more apt to occur in the course of an uneventful convalescence than otherwise. Have phlebitis and pulmonic embolism a common origin? Each, so far as can be determined at any rate, is aseptic, and each occurs typically after the most successful operations. It is possible that changes in the blood occur which are not evidenced by known methods of examining this tissue. But why should thrombosis of the left femoral occur so frequently after operations on the right side. That the two conditions are associated with each other and with some form of anæmia is to be suspected at least from the frequency of their occurrence in patients who have suffered prolonged hæmorrhage.

Care of the City Poor.

The Budapest Association for Improving the Condition of the Poor are doing a vast amount of good, and while they are necessarily expending a large amount of money it is more than saved when it is considered that the people whom this association is helping would fall to the care of the city hospitals. The following figures show the extent of the work:—37 mother and 81 children were taken recently to their summer home on the coast of the Adriatic Sea at a total expense of about £50. The association hopes to send several such groups from the crowded tenement districts. Twenty-five shillings will send a mother and baby to the seashore for a week.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

Belfast District Lunatic Asylum.—The annual report of this asylum, just issued, is as usual a most interesting document, for Dr. William Graham supplements the official statistics with his own comments, often of a most original nature. The daily average number of cases under treatment was 1,108, and the total admissions 241. As regards causation of mental disease, Dr. Graham says that heredity is given as the cause in 62 of the admissions, but this is only the way in which the insanity is transmitted, and does not explain the original cause. Seventeen cases were attributed to alcohol, but here again the statistics are not satisfactory, and Dr. Graham evidently agrees with the opinion, which he quotes, that about 50 per cent. of the cases are due to syphilis and alcohol. The recently published views of the Inspectors of Lunatics that the Irish race is particularly prone to mental disease drew some vigorously expressed opinions from Dr. Graham. "If the nation is in danger of becoming a nation of lunatics, it does not much matter who governs us, or how much land the peasant possesses," and such observations as the Inspectors have made call for the most serious attention. He thinks that there are no doubt preventable causes at work both in Ireland and America to bring about this degeneracy in the nervous system among the Irish in both countries, and that the race is not specially "contaminated with the virus of insanity." The Russian and Hungarian peasant, emigrating under much the same circumstances, does not show the same liability to insanity as do the Irish, and Dr. Graham suggests that this may be due to the greater mental activity of the last; his brightness of intellect, and keen susceptibility to joy and sorrow render him more liable to mental breakdown in the new conditions of life—the crowded tenements of big cities, and the keen competition for a livelihood. The ratio of recoveries to the total number of admissions was 28.6. Of the deaths, 15 were due to general paralysis of the insane, a disease a few years ago almost unknown in Ulster. As regards finance, it appears that after deducting receipts from paying patients and other sources the net capitation cost is £21 1s. 8d. per annum and the amount payable out of the general purposes fund of the city is £11 3s. 6d. for each patient chargeable to the ratepayers.

LETTER TO THE EDITOR.

AN APPEAL TO THE MEDICAL PROFESSION.

To the Editor of The Medical Press and Circular.

Sir,—Allow me to bring under your notice a distressing case that has occurred in this neighbourhood. In January last, Dr. J. P. Maguire was seized with sudden and severe illness, and succumbed to an attack of acute Bright's disease. He left a widow and a little boy, aged 10 years, quite destitute, and I am trying to get together enough money to pay for the widow's training as a midwifery nurse. The little boy we have a prospect of getting settled in a school near Dublin.

So far I have only applied locally, but the response has been so feeble I am forced to appeal to a larger public, the charitable members of the profession.

The following have already generously subscribed:

	£	s.	d.
Dr. Haurahan, Hollymount	2	2	0
Dr. Temple, Cong	1	1	0
Dr. F. Golding, Headford	1	1	0
Dr. A. Gill, Westport	1	1	0
Dr. Corcoran, Ballinrobe	1	1	0
Dr. Macaulay, Ballina	1	0	0
Dr. Costello, Tuam	1	0	0
Dr. McNulty, Killala	1	0	0
Surgeon-Gen. Joynt, Dublin	0	10	0
Dr. Hegarty, Clonbur	0	10	0
Dr. Mahon, Ballinrobe	3	3	0
Donation from Royal Medical Benevolent Fund	15	0	0
	£28	9	0

Of this sum, £4 has been disbursed for pressing necessities, leaving £24 9s. in hand. If this could be brought up to £50, it would enable us to place the widow in a position to support herself.

I am, Sir, yours truly,
R. B. Mahon.

Ballinrobe, Co. Mayo, Sept. 14th, 1907.

[We shall be very glad to receive subscriptions for this most deserving object, and we appeal to our readers for their aid. All subscriptions received will be acknowledged in the journal and forwarded to Dr. Mahon.—Ed., M.P. & C.)

OBITUARY.

CHARLES MACKINNON,, CLARK, M.D.Brux., M.R.C.S., L.R.C.P.

We regret to record the death of Dr. Charles Mackinnon Clark, which occurred at his residence, Rose Hill, Dorking, on September 4th. Dr. Clark, who was only 42 years of age, was taken ill soon after he began his summer holiday at Zermatt, in the early part of June, and is supposed to have contracted ptomaine poisoning. In the beginning of August he left for Cornwall, and at first he seemed to improve, but gradually he became worse again, and was brought home in a serious condition. He never regained his strength, and passed away exactly a week after his return home. Dr. Mackinnon Clark was very popular among all classes, and his death has caused much sorrow in the town, while sympathy is especially felt for his widow and their child. Educated at St. George's Hospital, Dr. M. Clark, after qualification, joined his father in his extensive practice at Dorking, and since his father's death he continued the practice alone. He was one of the honorary medical officers of the Dorking Cottage Hospital, and medical officer to the Dorking Oddfellows.

THOMAS LOGAN, M.D.Aber., AND F.P.S.Glasg.

We note with regret that the death took place on September 4th, of Dr. Thomas Logan, in his 67th year. Dr. Logan was educated for the medical profession at Glasgow and Aberdeen Universities, and on the completion of his medical course he was appointed superintendent of the Paisley Infirmary. He subsequently went into general practice in Dumfriesshire, where he was Medical Officer for the long period of twenty years for the parishes of Penpont, Keir, and Tynron. He then left that place to commence practice in Wibsey, near Bradford. At Wibsey, he was first partner with the late Dr. Warburton, and on his death succeeded to the practice as well as to all the public appointments connected with it. He was Medical Officer of Health for North Brierley; indeed, in the Wibsey district he was in public and private service there for twenty-five years. On his retirement he was entertained to a public banquet in the Midland Hotel at Bradford by lay and medical representatives of the city, the function being attended by many from north and south. Dr. Logan came to Harrogate about two years ago. He had for a long time been diligently engaged in scientific study, and it is hoped that the fruit of his labours in this direction will eventually be made public.

STUART NAIRNE, F.R.C.S.Ed., F.F.P.S.Glas.

We regret to announce the death of Dr. Stuart Nairne on September 8th, at his residence in Renfrew Street, Glasgow. A native of the burgh of Irvine, Dr. Nairne was educated at St. Paul's Parish School, at the Normal Training College in Dundas Vale, from which he passed to the University, where he took high honours and secured a £50 bursary in the chemistry class. At the close of his medical curriculum, Dr. Nairne began practice in Glasgow, his special interest lying in surgery. He conducted for some time a ladies' class for gynæcology in the Western Medical School, which was largely attended. Impressed with the great amount of suffering among women, he was the moving spirit in the foundation of the Samaritan Hospital for the free medical and surgical treatment of women. In association with Dr. George Halkett, the late Mr. Thomas Jenkins, and Mr. Thomas MacQuaker, the present secretary and treasurer of the hospital, and several other gentlemen, he formed the project in December, 1885, and on January 4th, 1886, the hospital was inaugurated by Lord Blythswood. Dr. Nairn was the first surgeon of the hospital and Dr. Halkett its first physician. He took a great interest in the recent extension of the institution, and he was present at the opening of the new section by Lady Blythswood in April last. On his retirement he was the recipient of a public testimonial, consisting of a cheque for about £300, a study chair, and of silver plate for Mrs. Nairne. Dr. Nairne was an occasional contributor to the medical journals, and in 1883 he published several medical works. Of the Glasgow Obstetrical and Gynæcological Society Dr. Nairne was the first honorary secterary. Dr. Nairne is survived by his wife, one son, and three daughters.

SPECIAL ARTICLE.

VITAL STATISTICS OF IRELAND.

The "Annual Report of the Registrar-General for Ireland" for the year 1906 contains little that can cause comfort even to the most optimistic. With a stationary death and marriage-rate, an increased emigration rate, and a progressively decreasing population, it is difficult to deduce any sign of prosperity from the Registrar-General's figures.

The number of marriages registered in Ireland during the year 1906 was 22,662; the number of births, 103,536; and the number of deaths, 74,427. The marriage-rate was 5.16 per 1,000 of the estimated population, showing a decrease of 0.10 as compared with that for the year 1905, but is 0.08 above the average rate for the ten years 1896-1905; the birth-rate was 23.6 per 1,000 of the estimated population, showing an increase of 0.2 as compared with that for the preceding year, and is 0.4 above the average rate for the ten years 1896-1905; and the death rate (17.0 per 1,000) is 0.1 under the rate for the preceding year, and 0.9 under the average rate for the ten years 1896-1905. The natural increase of population, or excess of births over deaths, was 29,109; the loss by emigration amounted to 35,344; it would appear, therefore, that there was a decrease of 6,235 in the population during the year, but against this decrease there is a set-off in immigration, of which there is no official record. Its effect is probably very slight.

The Registrar-General expresses regret that there is an increasing majority of instances in which the ages of the persons married are not stated, and in which the only information of age given is the word "minor" or the words "full age."

Of 22,662 men married during the year, 311, or 1.37 per cent., were minors; and of the women married 1,096, or 4.84 per cent., were under age. Of those married under age in 1906 the highest proportion of husbands (1.71 per cent.) was in the province of Leinster, and of wives (5.89 per cent.) in the province of Ulster. The percentage of persons married in Ireland, who were under age, is very far below the corresponding percentages in England and Scotland.

The highest marriage-rate for county, or county borough areas (7.9 per 1,000 of the population) was in the county borough of Dublin; and the lowest 3.1 in each of the counties of Clare and Mayo. Between these extremes the most favourable rates were 7.8 for the county borough of Belfast, 5.7 for the county of Dublin, and 5.6 for the county and county borough of Londonderry, and the least so 3.4 for the county of Galway, 3.4 for the county of Roscommon, and 3.8 for the county of Meath.

The 103,536 children whose births were registered in Ireland during the year 1906, include 100,845, or 97.4 per cent. who were legitimate, and 2,691, or 2.6 per cent. who were illegitimate, being equal to the corresponding average percentages for the preceding 10 years. These results compare favourably with the returns for most other countries.

The proportion of illegitimate children is as usual highest in Ulster, and lowest in Connaught, the rates for the four provinces being:—Ulster, 3.5 per cent.; Leinster, 2.7; Munster, 2.2; Connaught, 0.7.

Taking the county or county borough areas, the four highest birth-rates were 33.0 for Dublin county borough; 31.2 for Belfast county borough; 24.4 for county Kildare; and 24.1 for county Antrim. The four lowest rates were—18.3 for county Cavan; 18.4 for Queen's county; 18.7 for county Roscommon; and 19.0 for county Longford.

During the year 1906 the number of deaths registered in Ireland was 74,427, equivalent to 1 in 59, or 17.0 per 1,000 of the population estimated to the middle of the year. The deaths of males amounted to 37,131, and those of females to 37,296, the rate per 1,000 males and 1,000 females, respectively, being 17.1 and 16.9.

The five county or county borough areas having the lowest mortality rates per 1,000 of the population were:—County Mayo, 11.7; county Leitrim, 12.0; county Galway, 12.8; county Kerry, 12.9; and county Roscommon, 13.1. The highest rates are as follows:—Dublin county borough, 25.0; Belfast county borough, 20.6; county Armagh, 19.0; county Monaghan, 18.9; and county Down, 18.1.

More than 14 per cent. of the deaths registered took place in workhouses or workhouse hospitals.

As usual Mr. Matheson represents by a diagram the principal causes of death operative during the year. Tuberculosis again presents the highest column with 11,756 deaths, old age coming next with 8,409. In discussing the incidence of zymotic diseases the Registrar-General comments on the great decline in the mortality from enteric fever. The number of deaths from this disease was only 394, as against an annual average of 755 for the 10 years 1896-1905. In 1898, no fewer than 1,284 of the inhabitants of Ireland died of enteric fever. Of the deaths in 1906, 97 were registered in Belfast county borough, and 48 in Dublin county borough.

The deaths from typhus have during the past two years shown a tendency to increase in number. They declined from 128 in 1900 to 53 in 1904, rose in 1905 to 68, and last year to 86.

There was in 1906 a high mortality from diarrhœal diseases, the deaths registered mounting to 1,675. Of these, 379 occurred in Belfast, and 359 in Dublin.

There has been no death from rabies since 1898.

To the subject of tubercular diseases the Registrar-General devotes careful attention, and those interested in the campaign against tuberculosis cannot fail to be grateful to him for his graphic representation of facts and his strong comments thereon. He attempts to draw the special attention of the Lord Lieutenant to the matter, and goes on:—

"In introducing this subject, I may state that the fall of the mortality rate for tuberculous disease in England and Wales during the 42 years from 1864 to 1905, as may be seen in the diagram facing this page, is a proof that the disease is at least capable of being successfully combated, and for the purposes of the militant sanitarian may be looked upon as a preventable disease. I cannot, your Excellency, say that it is a matter of much congratulation that the high death rate of 2.9 per 1,000 in the year 1904 for all forms of tuberculous disease has declined to 2.7 per 1,000 in the years 1905 and 1906. When I come to enumerate the figures which I have compiled, I find that there were 11,756 victims, inhabitants of Ireland; in other words, out of a total of 74,427 deaths registered in Ireland during the year 1906, no less than 11,756, or 15.8 per cent., were sacrificed to a disease which is in a great degree preventable. It is a difficult matter for me to dissociate myself from responsibility in such appalling circumstances, and I cannot feel that my duty terminates in merely collecting and classifying these most depressing statistics. Year after year these facts are published, and although the members of the medical profession are strenuous in trying to awaken the public mind to a state of affairs that can only be considered as destructive to the community, yet, comparatively speaking, our countrymen are not alive to the dangers which threaten them. Our people have shown that they are not slow to appreciate the benefits of vaccination as a protection from small-pox, and when they are thoroughly awakened as to the infectious character of tuberculous disease they will be the first themselves to aid in its prevention."

The diagram comparing the condition of affairs in Ireland with that in England and Scotland shows that, while in England the rate has declined from 3.3 per 1,000 in 1864 to 1.6 per 1,000 in 1905, and in Scotland from 3.6 per 1,000 in 1864 to 2.1 per 1,000 in 1905, it has risen in Ireland from 2.4 per 1,000 in 1864, to 2.9 in 1904 and to 2.7 per 1,000 in 1905 and 1906.

The number of deaths due to phthisis was 8,933, and it is noticeable that the highest incidence was between the ages of 25 and 35.

Mr. Matheson mentions that "the large proportion of uncertified deaths in Ireland (24.4 per cent. of all deaths registered) during the year 1906 is a matter of grave importance both from the public point of view, as well as from the point of view of the profession of medicine." But there is little doubt that the explanation lies in the fact stated by him that a custom prevails in many parts of the country of not seeking medical advice, especially for the aged and those suffering from chronic forms of disease. The large number of persons returned as dying of "old age" bears out this view. The total number of deaths from accident, homicide, and suicide which were recorded in the death registers of Ireland in the year 1906 was 1,875—by accident 1,685, by homicide 43, and by suicide 147 deaths. Of the total deaths attributed to accidental circumstances, 1,126 were of males and 559 were of females. With this number of deaths as the result of violence, we fail to understand why there is record of only 1,788 inquests.

Mr. Matheson furnishes fuller information on the subject of infant mortality than has been his custom heretofore. Two illustrative diagrams give respectively the comparative infant mortality curves of the three countries, and the effects of fourteen principal causes in producing infant mortality in Ireland. In addition, he furnishes a map showing the relative rates in the different unions throughout Ireland. In the rural districts there is, of course, a low rate of infant mortality, but in the town districts it is high. The rate for the 22 chief town districts is 135.02 per 1,000 children born, dying in the year. In the aggregate, however, the infant mortality rate of Ireland compares favourably with that of other countries. In England and Wales the infant mortality rate, which in 1864 was 153 per 1,000 births registered, was 133 in 1906; that in Scotland in 1864 the rate was 126, and in 1905 it was 116; while the infant mortality rate for Ireland in 1864 was 98 per 1,000 births registered, and in the years 1904, 1905, and 1906 the rates were 100, 95 and 93 respectively.

The general arrangement of Mr. Matheson's report is, as usual, excellent, and gratitude is due to him, as well as to Dr. Ninian Falkiner, Medical Superintendent of Statistics, for the interesting manner in which information is given to the public.

REVIEWS OF BOOKS.

THE NURSLING. (a)

Professor Budin's last work has a peculiar fascination in that it gathers up the threads of a lifetime's toil and places on record the thoughts and opinions of an enthusiast who made the subject of which he treats peculiarly his own. It may be owing to France's need for population that infant-rearing has been studied so carefully in that country, but certain it is that we have as yet very little to show in Great Britain to match in interest or importance the organisation that is springing up in that country for the care and protection of the infant. These practical results are the outcome of the efforts of the school of obstetrics of which Pinard and Budin were the foremost teachers, and in the placing of infant-culture on a scientific basis the last-named must ever take the credit due to the pioneer. What Budin's difficulties must have been we are not told, but we can imagine him triumphing over them all with that genial optimism and delighted confidence which are so strongly in evidence in this book. It is, indeed, just the sort of book it takes a Frenchman to write—original, clever, logical, even brilliant, so that the reader puts it down with a sigh at his own denseness for not knowing how easy it is after all to rear premature and weakly children. But on second thoughts he begins to doubt whether it is so easy, and to wonder whether the genial professor does not see everything through *couleur de rose* spectacles. Indeed, we have here in this book something more than a mere professor; the author is half Santa Claus, half fairy godmother. Is anything wrong with the baby? In pain? Sick? So, a few kind remarks, a gentle turn of the wrist, and lo! it is well. But for all that let Professor Budin be optimistic. It is the optimist who conquers the world, and this work of his has gone a long way towards systematising and placing on sure ground the rearing of the babies of the State, and if we do not agree with him in his estimate of sterilised milk, and in all his other opinions, we can truthfully say that this is the most important work on the subject that has yet been published, and that if France is ever again to have a *grande armée* whether of war or of industry, she will owe it more to Budin than to the doctrinaires who prate in their armchairs of falling birth-rates.

A TREATISE ON ORTHOPÆDIC SURGERY. (a)

In this "Treatise on Orthopædic Surgery," the author, Dr. Whitman, has succeeded in presenting the subject in a most interesting and instructive form. The general appreciation of this fact is no doubt the reason why this work has now attained its third edition.

In dealing with disabilities and deformities one is led by the author to the rational method of their treatment, by a study of the particular affection from an ætiological and mechanical point of view. For instance, in the chapter on Weak or Flat Foot, where, perhaps, we can form the best idea of the way in which the subject is treated, we find paragraphs under the following headings: General description of the foot and of its functions, the arches, the foot as a passive support, in activity—Improper postures—Movements—Function of the muscles—Strength of the muscles (with tables)—The foot as a mechanism—The weak foot or so-called flat foot—Description—Anatomy—Pathology — Etiology — Statistics — Symptoms—Diagnosis—Varieties—Weak foot in children—Exceptional forms—Treatment — Preventive — Exercises—Support—Construction of brace—The rigid weak foot—Forcible correction of deformity—Subsequent treatment—Adjuncts in treatment—Operative treatment. In the work generally, operative treatment (by the knife) is briefly indicated, and, as a rule, not given in detail. We may say that each section is lucid, concise, and to the purpose, making the work a useful acquisition to the student, the general practitioner and worker in this special branch of surgery.

It is a difficult matter in a review to touch on all the excellent qualities that might be alluded to in this work. Considerable attention has been paid to the methods of examining, measuring, and recording deformities. Also careful descriptions are given of exercises, manipulations, and apparatus used in their treatment—a subject that is not always dealt with in so thorough a manner as it is here. But in this connection, more might certainly have been said with advantage on the manipulative treatment of congenital club foot.

In conclusion, this Orthopædic Surgery contains 554 well chosen illustrations, mostly reproductions of photographs, and some skiagraphs. These numerous illustrations, though not an essential part of the work, as it is in some of the more recent medical text-books, especially from America, add very materially to the value and utility of the book.

ADAMSON ON SKIN DISEASES. (b)

As a "practical guide to the clinical study and treatment of skin affections in children" Dr. Adamson has produced a book "based very largely" upon his own personal experience, and, in common with other works of a like character, it suffers from a certain want of balance. We must confess that we expected to find it brimming over with descriptions of cutaneous lesions and manifestations such as are only found in childhood, but, although some of the disorders treated of are dealt with from the point of view as they appear at this age, sufficient stress is not laid upon the clinical differences between skin affections of children and adults. The best part of the book is that dealing with ringworm of the scalp and its treatment by the X-rays. The chapter on eczema is also good, the author taking the view that "an affection which is primarily microbic is not eczema." He has retained the not altogether satisfactory term, "tuberculous eczema," while admitting that the type thereunder described has no relation, in his opinion, to tuberculosis. It is rightly stated that the key-note of successful treatment in infantile eczema is protection from irritation, and that unless this be adequately secured the best remedies will fail in their action. The supposed danger of curing an eczema in childhood rapidly is not treated very seriously, and no caution is specially advocated against employing powerful or toxic remedies over large eczematous areas. Only two lines are devoted to caterpillar-rashes which, if not very important, have attracted considerable attention both in this country and also in America. The harvest-bug is not mentioned, though its lesions are common enough among children who romp in cornfields and play among hayricks in summer. The photographic illustrations are excellent, and there is a useful list of formulæ appended. The index might with advantage have been much fuller.

(a) "The Nursling: the Feeding and Hygiene of Premature and Full-term Infants." By Pierre Budin, Professor of Obstetrics, University of Paris. Authorised Translation by William Maloney, M.B., Ch.B. With an Introduction by Sir Alexander R. Simpson, M.D., LL.D., D.Sc. 111 diagrams in colour. London: The Caxton Publishing Co. 1907.

(a) "A Treatise on Orthopædic Surgery." By Royal Whitman, M.D., Clinical Lecturer and Instructor in Orthopædic Surgery in the College of Physicians and Surgeons of Columbia University, New York, &c. Illustrated with 554 engravings. Pp. xii. and 871. London: Henry Kimpton. 1907.

(b) "Skin Affections in Childhood." By H. G. Adamson, M.D., M.R.C.P., Physician for Diseases of the Skin, Paddington Green Children's Hospital, and the North-Eastern Hospital for Children. Oxford: Henry Frowde. London: Hodder and Stoughton. Pp. xvi. and 287. Illustrated. Price 5s. net.

TICS AND THEIR TREATMENT. (*a*)

THE translator has conferred a service on his colleagues by publishing this important work. The authors favour the distinction, originally observed by Willis, between continuous, permanent tonic convulsions, and intermittent, momentary clonic movements. They regard the use of the epithet "convulsive" as superfluous, and prefer to employ the term "tic" by itself, save in such cases as it may be found absolutely necessary to indicate the precise nature of the muscular contraction. The pathogenesis of tic is discussed in the third chapter. In this connection, a very careful distinction is drawn between the two terms "tic" and "spasm," which are so apt to be used indifferently as if they implied the same condition. A tic is a co-ordinated, systematised, and purposive act. It results from voluntary repetition of the same movement by the patient; but mere repetition is not sufficient to evolve a tic in every case. Psychical predisposition is absolutely essential in the form of volitional enfeeblement, and the authors lay considerable stress on the important bearing of mental insufficiency.

The different tics are arranged and discussed under separate headings, such as facial, auditory, vision and arm tics. Numerous cases are given in illustration of these varieties. The treatment of tics naturally comes in for a considerable share of attention. To neglect them or to consider them incurable is entirely unwarranted. Drugs are of little value. Diet and general hygiene must be attended to, while hydrotherapy is always of service. Massage ought to be given a trial; but the use of mechanical apparatus in order to avert muscular insufficiency is deprecated, as is also electricity in all its forms. Hypnotic suggestion is very useful in some cases. Re-education is the only really valuable form of treatment, and the writers detail the exercises which the patient should in every case be made to carry out. He must be made to perform certain slow, regular, and accurate movements limited to the muscles of the area involved. These exercises must not be too prolonged. In addition, the patient should be required to remain absolutely motionless for a few seconds at a time. Other additional measures such as rest in bed and isolation are not generally commendable. The translator has done his work well, and the book has been excellently turned out by the publisher.

GENERAL SURGERY. (*b*)

THIS ambitious attempt to summarise all recent contributions of importance in the domain of surgery will doubltess be appreciated by "pure" surgeons. For the general practitioner its interest will probably not be so great. It at any rate serves the purpose of indicating the trend of present-day surgical procedure in the various departments. The task of selecting and summarising the material seems to have been very judiciously performed and, indeed, it would hardly be otherwise in the hands of such an accomplished and experienced editor as Mr. Murphy, whose fame is world-wide. There are a fair number of illustrations and diagrams in elucidation of the text.

We can quite believe, as stated by the editor, that the advance in the year's annual output of medical literature put his powers of discrimination each year to a severer test. Still, great advantage attached to such a summary if only because no ordinary person could possibly command so comprehensive a view of contemporaneous work and thought. One has only to look through the admirable synopsis of tuberculous literature to grasp the importance of the work here recorded. Text-books of the present day so rapidly go old in the sense of failing to remain abreast of the times that some such work as this is a well-nigh indispensable companion to the ordinary works of reference. Every practitioner wants, for instance, to post himself in the latest news or data concerning epidemic cerebro-spinal meningitis (which is dealt with here as distinct from "spotted fever."). Malta fever is fast becoming a subject of interest now that its existence in widely distant areas has been demonstrated, with the promise of a further spread.

It may be that the practitioner of the future will prefer this methodical way of adding to his store of information instead of taking it by tablespoonfuls in the medical journals, but after all the synopsis cannot replace that from which it draws its being, *e.g.*, contemporaneous medical literature.

MEDICAL NEWS IN BRIEF.

Award of Medals for Tropical Medicine Research.

THE Mary Kingsley medal, instituted by the Liverpool School of Tropical Medicine in memory of Miss Mary Kingsley, who died in 1900, has been presented to the gentlemen mentioned below for work of special research into tropical medicine:—

1. Colonel David Bruce, F.R.S., C.B., Royal Army Medical Corps, who in 1887 discovered the cause of Malta fever, and proved that that malady was produced by the milk of infected goats.
2. Professor Dr. Robert Koch, Nöbel Laureate, who ascertained the cause of cholera, and who has contributed much to the knowledge of tropical diseases, especially the discovery of the frequency of malarial infection in children.
3. Dr. A. Laveran, Pasteur Institute, Paris, and D.Sc., University of Liverpool, who in 1880 made the great discovery that malarial fever is caused by parasites in blood.
4. Sir Patrick Manson, F.R.S., K.C.M.G., London School of Tropical Medicine, who in 1878 discovered that one of the parasites of man belonging to the group of *Filaria* is carried by a kind of mosquito.
5. Dr. Basile Danilswsky, Professor of Physiology, University of Kharkoff, who discovered numerous parasites of blood in a large number of animals shortly after Laveran's discovery was made.
6. Dr. Charles Finlay, chief sanitary officer of Cuba, who in 1880 originated the theory that yellow fever is carried by mosquitoes.
7. Dr. Camirlo Golgi, Professor of Pathology, University of Pavia, who in 1887 made a complete study of the life cycle of parasites of malaria.
8. Colonel W. C. Gorgas, United States Army, who, as chief sanitary officer of Havana gave practical effect in 1902 to the discoveries of Finlay and of the American commission in connection with yellow fever, and succeeded in banishing the disease from the city.
9. Waldemar Mordecai W. Haffkine, C.I.E., who in 1893 discovered a method of inoculation beneficially used in India.

(*a*) "Tics and Their Treatment." By Henry Meige and E. Feindel. With a preface by Professor Brissaud. Translated and Edited with a Critical Appendix by S. A. K. Wilson, M.A., M.B., B.Sc., Resident Medical Officer, National Hospital for the Paralysed and Epileptic London: Sidney Appleton. 1907.

(*b*) "Practical Medicine Series." Edited by Gustavus P. Head, M.D., Professor of Laryngology and Rhinology at the Chicago Post-Graduate Medical School. Vol. II.—General Surgery. Edited by John B. Murphy, A.M., M.D., LL.D., Professor of Surgery in Rush Medical College. Series 1906. Chicago: The Year Book Publishers Glasgow: Gillies. Vols. I. and VI.—"General Medicine." Edited by Frank Billings M.S., M.D., Dean of the Faculty of Rush Medical College, and J. H. Salisbury, A.M., M.D., Professor of Medicine, Chicago Clinical School.

10. Dr. Arthur Loos, Professor of Parasitology, School of Medicine, Cairo, for work in connection with parasitology.

11. Dr. Theobald Smith, Professor of Comparative Pathology, Harvard University, who in 1893 discovered a new kind of blood parasite in the so-called Texas cattle-fever.

Yet Another Medical Manifesto.

Miss May Yates, hon. secretary of the Bread and Food Reform League, sends us a copy of a manifesto on the subject of food which has been signed by members of the medical profession and scientific societies. In this they say:—

"We desire to endorse the opinion expressed in the report of the Inter-Departmental Committee on Physical Deterioration that insufficient and improper food is a prominent factor in the causes to which degenerative tendencies might be ascribed, and that it also tends to produce a craving for drink.

"As the report shows that there is a very large amount of ignorance about the right choice and proper preparation of food, and as much distress would be lessened by a knowledge of foods which nourish completely at the least cost, we venture to urge the Lord Mayors and Mayors of London and of other cities and towns, all municipal authorities, societies, and individuals interested in ameliorating the condition of the people to direct attention to this important subject.

"Without advocating any special system of diet, we urge teaching the economic and nutritive value of much-neglected staple foods such as oatmeal, wheatmeal, barley, rice, maize, peas, beans, lentils, nuts, fresh and dried fruits, green and root vegetables, as their more general use would promote the health of all classes of society."

The manifesto is signed by, among others, Sir James Crichton-Browne, A.R.S., Sir Lauder Brunton, F.R.S., Dr. John Beddoe, F.R.S., Mr. Edward Berdoe, Sir William Crookes, F.R.S., Mr. A. D. Fripp, K.C.V.O., C.B., Mr. A. Pearce Gould, Mr. George Henslow, Dr. Robert Hutchinson, Dr. Robert Miller, Dr. W. R. Smith, Mr. W. B Tegetmeier, F.L.S., Dr. Sims Woodhead, and Sir Samuel Wilks, Bart., F.R.S.

Signatures in support should be sent to Miss Yates at 42a, Bloomsbury Square, London, W.C.

Infantile Mortality Congress.

The second international congress of authorities and societies interested in the milk supply and the protection of children against disease has been sitting in Brussels. Fourteen Continental and other Governments have sent official delegates. The British Government sent no official representatives, but both Australia and Canada did so. England was, however, represented informally by the following ladies and gentlemen: Drs. MacCleary, Taylor, and Liell, Miss Marion Fitzgerald, Mrs. L. J. Greenwood, Councillor W. Fleming Anderson, Dr. A. K. Chalmers, Alderman Broadbent and Dr. S. G. Moore, Dr. James Niven and Miss M. G. Taylor, Councillor Dr. Cullen, Dr. J. Milson Rhodes, Miss Zannetti, Dr. MacIntyre, Dr. Sydney Davies, representing the Associated National Conference of England on Infantile Mortality. Dr. L. Coit represented the American Association for the Control of the Milk Supply, and other kindred societies of the United States. A feature of the congress consisted in the practical demonstrations held at the Arts and Crafts Exhibition, now in progress at the Cinquantenaire, of the Pasteurisation of milk according to the method introduced by Mr. Nathan Straus in New York. The system of Mr. Straus is best described in a paper distributed at the congress.

London Consumption Conference.

A conference of representatives of metropolitan, city, and borough councils was lately held at the instance of the Paddington Council, at the Town Hall, to consider the best methods of preventing pulmonary tuberculosis, and various resolutions, including one in favour of compulsory notification, were adopted. These were sent to the President of the Local Government Board with a request that he would receive a deputation from the conference. Mr. Burns replied that "The subject (prevention of consumption) has received the serious attention of the Board, and a report on the matter is being prepared in their medical department, which they hope will shortly be issued. In the meantime, it does not appear to the President to be necessary that he should trouble the deputation to attend, but he will be prepared to consider any further statement which the councils may wish to submit to him in writing." Mr. A. W. J. Russell, Town Clerk of Paddington, honorary secretary of the conference, has, on its behalf, again asked Mr. Burns to receive a deputation. Sir G. Fardell and Mr. L. G. C. Money, the Members of Parliament for Paddington, have been requested to co-operate in securing a revision of the President's decision.

The Proposed "Tuberculosis Exhibition" in Dublin.

A meeting of the Consultative Committee of the Tuberculosis Exhibition, to be held under the auspices of the Women's National Health Association of Ireland at the Home Industries Section of the Exhibition, Dublin, in October next, was held recently in the Leinster House, Kildare Street.

Her Excellency the Countess of Aberdeen, President of the Association, occupied the chair, and opened the proceedings with a short speech, in which she detailed the objects of the Exhibition. Short descriptions were then given by the organisers of the different sections of the nature of their sections. Amongst the speakers were Professor McWeeney, Dr. Lily Baker, Dr. A. Boyd and Dr. W. J. Thompson. Sir Henry Swanzy, president of the Royal College of Surgeons then proposed a resolution approving of the steps taken by the Executive Committee with the object of forming a representative and instructive collection of objects illustrating in a popular manner the subject of tuberculosis and its prevention, and pledging themselves to do all in their power to make the forthcoming Tuberculosis Exhibition a success. This was adopted, and Dr. W. Calwell, Belfast, representing the Ulster Medical Society, moved a resolution commending the Tuberculosis Exhibition to the support of Irish public bodies and philanthropic organisations, and urging that steps should be taken to induce visitors to inspect it. This was carried unanimously, and after a vote of thanks to her Excellency for presiding the meeting ended.

Royal College of Surgeons in Ireland.

The second post-graduate course at the Royal College of Surgeons in Ireland will commence on September 23rd, and continue until October 15th. As almost the entire clinical material in Dublin will be available for purposes of instruction, the course should prove to be of the greatest value to medical men who desire to freshen up their knowledge and to keep abreast of the times.

We have received the Annual Illustrated Guide of the London and South-Western Railway (price 1d.), and we can cordially recommend it to the notice of those thinking of spending a holiday in the delightful country served by that line. The Guide is exceedingly well printed, illustrated, and got up, and it furnishes a large amount of useful information about the chief towns in the South-West of England. Nor is the Continent forgotten, and prospective tourists will find helpful descriptions of Paris and the Riviera to aid and guide them. Altogether it is quite a "monster" pennyworth.

Between 20 and 30 persons at Tollesbury and others at Wigborough, Peldon, Layer, Birch, and Salcot, have developed illness after eating brawn. Among the sufferers is the Rev. F. E. Crate, curate-in-charge at Salcot, and his family. Dr. Thresh is making investigations into the cause of the malady.

The Committee of the National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis are about to open the second half of their main building at Benenden, Kent, which will accommodate 68 patients.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

The Transvesical Operation for the Relief of Prostatism.—C. Bowers, in a paper (*American Medicine*, July) on the relief of prostatism in the aged male, calls attention to the fact that a number of old men have enlarged prostates—some 60 per cent.—but of these not more than some 15 per cent. suffer from prostatism; on the other hand, many people suffer from prostatism whose prostates are not enlarged, the condition in these cases being caused by a contracture at the neck of the bladder. This may give rise to the same symptoms as an enlarged prostate does, and in many cases prostates are removed for such a condition, in which a much less severe operation would have sufficed to cure the patient. The writer does not think that it is possible to make a certain diagnosis of this contracted condition of the neck of the bladder without a digital examination, made through a suprapubic wound. The most noted changes associated with prostatism are—bulging of the posterior commisure, lengthening in, and distortion of the prostatic urethra, with some sclerosis of the prostate itself, and contracture of the neck of the bladder. This last condition being present in most cases and being the most important of the anatomical changes, is largely responsible for the symptoms of retention, congestion and inflammation at the neck of the bladder. The author is firmly convinced that the suprapubic method is far better for exploring the bladder than the perineal, and that more conservative and rational operations will yield better results, and lower the mortality of the former operation to equal or less than that of the perineal route. An exact diagnosis can in many cases only be made on the exposure of the vesical outlet. The suprapubic route is as rationally indicated for the relief of such obstructive lesions at the urinary outlet, as it is in the case of vesical calculus, the perineal operation offering only 30 per cent. of cures, with 1·07 per cent. mortality, and a 50 per cent. chance of having exchanged one urinary difficulty for another, and not infrequently a lesser for a greater one. The transvesical operation entirely relieves all who survive of their urinary troubles, if due to obstruction in or about the vesical outlet, except when carcinomatous in character. The controversy that is now going on relative to perineal and suprapubic prostatectomy is only a repetition of the one waged when lithotomy was undergoing its evolution. No one to-day cuts for stone in the male bladder per perineum. It is most essential that the profession should recognise, first, that prostatism is due to other causes than hypertrophy of the prostate gland, secondly, that the transvesical operation for prostatism has attained a sufficient degree of perfection to be recommended to this class of pitiable sufferers, with the assurance of cure if availed of before the inflammatory process has reached the kidney, and arrested its functional activity; thirdly, that such cases should not be submitted to catheterism in the future, as they have in the past, until it is hopeless to interfere surgically. G.

Fibrolysin in Abdominal Adhesions.—Emmerlich (*Allg. Med. Zeitung*, March) records the case of a man who had been severely injured in the upper part of the abdomen seven years before; this injury was followed by numerous adhesions forming about the stomach and intestines. A laparotomy was done, and these adhesions separated as well as possible, but in a short time the symptoms began again and finally the patient became worse than ever, the bowels only moving after strong doses of purgative medicine, and such medicine always caused intense pain before the bowels acted. Fifty injections of Merck's fibrolysin were given, into the subcutaneous tissue of the upper part of the abdominal wall, at first, but as this proved painful, they were afterwards given in the gluteal region, the patient's chief complaint being the strong taste of fibrolysin he felt in his mouth for some time after each injection. At the end of the course the bowels acted daily, without the aid of any aperients. Five months after the last injection, digestion was perfect, and defæcation quite painless and normal, so the cure is in all probability a permanent one. G.

Plumbism Following Bullet Wounds.—Professor Braatz (*Munch. Wed. Woch.*, May, 1907) relates the case of a beater, who received a charge of shot in both legs. This accident was followed in a few weeks by the onset of severe symptoms of plumbism, including neuralgia in the legs and both trigeminal nerves. There was such severe stomatitis, that the dental fangs were surrounded by pus, and twenty-four teeth were extracted. There were tremors in the fingers and tongue. In a very short time the patient lost nearly three stone in weight. The X-ray examination of the leg showed that there were only seven small pellets imbedded in the patient's leg. Only six other similar cases are recorded, and from them it is evident that the diagnosis is rendered unusually difficult by the apparent capriciousness with which plumbism occurs after such bullet wounds. Large bullets may remain in the body for years and give rise to no symptoms; in other cases a few grains of shot after lying latent for years, or within a week or two of the time they were imbedded in the patient, may give rise to a sudden attack of severe plumbism. Sometimes the onset is extremely insidious, one symptom after another appearing in the course of years. In doubtful cases the blood should be examined for basophile granules in the erythrocytes. G.

The Treatment of Chronic Constipation with Regulin.—(*Theapic d. Gegenwart*, May, 1907).—Meyers' results from the use of regulin (agar-agar plus a small amount of cascara) in the treatment of chronic constipation have been excellent, like those of most previous writers on the subject. Out of 71 cases 62 were favourably influenced, so that he considers it by far the best drug for constipation. Its special advantages lie in the fact that it is not necessary to increase the dose after long continued use, and that its action is almost wholly mechanical. The dose is a teaspoonful to three dessertspoonsful a day, according to circumstances. It is best given in soup, mashed potato, or apple sauce. D.

A New Cutaneous Reaction in Tuberculosis.—Von Pirquet (*Berl. Klin. Woch.*, May 20, 1907) found that if tuberculin is introduced into the skin of a tuberculous child there will appear at the point a small papule not unlike the papule of vaccination, at first bright, later more dark red, and lasting about eight days. A small quantity, about two drops, of diluted tuberculin (old) is placed on the skin and a small scarification is made with a sterile lancet right through the drop. Von Pirquet has made 500 tests and obtained a positive reaction in nearly all the cases of clinical tuberculosis in infants. It was not absent in any case of miliary tuberculosis or of tuberculous meningitis in the last stage, or in infants markedly cachectic. The most characteristic reaction was obtained in cases of tuberculosis of the bones and glands. The reaction possesses diagnostic value, principally in the case of patients in the first year of life, and here it may prove of great value in the diagnosis of tuberculosis. In tuberculous animals a similar reaction becoming positive and distinct in twenty-four hours is obtained. The reaction may be regarded as indicating an increased degree of sensitiveness of the skin to infectious material on the part of those suffering at the time with actual infection by the corresponding microbe. D.

Tetany.—Chovstek (*Wien. Med. Woch.*, No. 23) says that all those factors which previously have been considered as being the etiological cause, are merely exciting causes. In individuals affected with tetany, the onset of menstruation, an angina, or, as the author has seen, the injection of tuberculin, is sufficient to excite an attack. The specific cause of the reaction in tetanic individuals is a constitutional one, and is probably associated with a functional disturbance of the parathyroid glands. D.

Suprarenal Hæmorrhage: A Usual Cause of Sudden Death.—Munson (*Jour. Am. Assoc.*, July, 1907) reports a case of collapse and death in which at autopsy the cause was found to be hæmorrhage in both suprarenal glands. Suprarenal hæmorrhage is said to be very common in still-born and very young infants, but in adults it is comparatively rare. Clinically the cases simulated peritonitis or internal hæmorrhage and show symptoms of suprarenal insufficiency (*i.e.*, prostration, loss of weight, diarrhœa) or resemble apoplexy. D.

Lupus Vulgaris Secondary to Tubercular Lymph Glands.—Jones (*Brit. Journ. of Dermatology*, September, 1907) discusses the origin of this disease in the light of an analysis of the cases treated in the light department of the London Hospital. The 923 cases so collected are divided into six groups: (1) 47.3 per cent. begin as a small spot on the face, cheek, or neck; (2) 28.9 per cent. begin on the nose or in the nostril; (3) 11.4 per cent. are secondary to tuberculous glands, either in the scar or in gland-abscesses; (4) 1.8 per cent. arise from mucous membranes, other than the nasal, chiefly the margins of the lips; (5) 1.8 per cent, secondary to tuberculous disease of bone; (6) 8.5 per cent. arise in miscellaneous ways and on various parts of the body. In this connection it is interesting to note that quite a number of patients gave a definite history of the disease, first beginning as a swelling on the cheek, about an inch and a half outside and three-quarters of an inch above the angle of the mouth. The patients stated that this swelling burst and the disease started from that. Dr. Jones says: "Naturally it strikes one that this was primarily a tuberculous focus in the subcutaneous tissue of that region, and possibly a tuberculous lymphatic gland. Such a gland is described by Pourrier, lying on the buccinator muscle, called the facial gland, and believed to drain the region about the angle of the mouth, both inside and out. ('Lymphatics' by Pourrier, translated by Leaf, Chap. V., 2.)" K.

Fatal Case of Acute Lupus Erythematosis.—Short (*Brit. Journ. of Dermatology*, August, 1907) reports a case of this disease which was first described by Kaposi, but which is very unusual in this country. The patient, a woman, æt. 28, gave a history of four months' illness on admission to hospital, when she presented a condition of diffuse swelling at the bridge of the nose and adjacent parts, and over the left malar region a reddened patch about the size of half-a-crown. The first sign of the disease was noticed on the tips of the fingers and toes and on the lobules of the ears where the skin became covered with coarse scales of a dark red colour. On admission the finger tips and toes were red and desquamating and there was slight œdema of the feet. A week later small blebs containing pus appeared on the side of one finger and of one toe near the nails, and the eruption on the face spread considerably and became covered with herpetiform blebs which dried up into crusts. After this small rings of follicular ulcers appeared on the roof of the mouth, the vulvæ became œdematous, and the lymphatic glands generally enlarged, hard and tender. The temperature averaged about 101° F. Five weeks after admission the patient had a convulsion and became unconscious, after which she vomited and her condition improved for a time. A week later the vomiting began again, the face swelled, herpes appeared and, after a few days, twitchings and convulsions were of almost daily occurrence. In the gluteal region several painful subcutaneous nodules appeared, the patient developed pneumonia, and died eight weeks after admission. The urine was always of low specific gravity, pale in colour, reduced in quantity, and contained a small amount of albumen. K.

The Beneficial Effect of One Disease on Another.—Bury. (*The Med. Chronicle*, August, 1907) reports two cases in which it appeared that the occurrence of a second disease had a markedly beneficial effect on an already existing disease from which the patient was suffering. The first patient was a man æt. 44, who was admitted to hospital with symptoms of cardiac muscle failure and signs of mitral regurgitation. This patient remained in hospital for seven weeks without any improvement, at the end of which time he was so bad as to need subcutaneous injections of strychnine. Infection resulted from one of these injections and the patient developed a severe cellulitis of the arm which ended in suppuration. From the date of the onset of the suppuration the cardiac symptoms improved, and shortly after he left the hospital apparently quite well. The second case was that of a man admitted to hospital with symptoms of insular sclerosis, including marked hemi-atrophy of the tongue. He was discharged without much change, but sometime after he had a severe attack of smallpox, on recovery from which his former symptoms began to disappear and in a few weeks he was quite well. Dr. Bury saw him three and a half years later, and says he "could detect nothing wrong with his limbs; the gait was normal; there was no nystagmus and no difficulty in speech. The left half of the tongue, however, was still atrophied." K.

Thiokol and Myrtol.—Dibailow (*Russ. Pract., Avzt.*, 1907. No. 24) has employed these drugs in chronic bronchitis and pneumonia. They were at first used for pulmonary tuberculosis, but more extended experience seems to show that they are valueless in that disease. The present writer has obtained most satisfactory results in 53 cases of bronchitis, and five cases of lobar pneumonia with thiokol. The doses varied from two to seven grains three times daily after meals. The improvement noted consisted in a diminution of the sputum, a lessening of the dyspnœa, and a practical cessation of coughing. None of the objectional symptoms described by Rossi, such as vomiting and headache, were observed. Myrtol was used in 26 cases of chronic bronchitis, the drug being administered in two-grain doses in gelatine capsules. It was well borne and seemed to exert a similar effect to that of thiokol, but less marked. It was particularly useful in fœtid bronchitis. M.

Veronal as a Hypnotic.—As a result of 78 careful observations, and after a study of the literature, Likudy concludes (*Russ. Med. Rundschau*, 1907, Heft. 6., p. 362), that veronal is the best of the newer hypnotics, and formulates the following statements:—(1) Veronal is characterised by the harmlessness and certainty of its action; in 78 per cent. of all cases its action is efficient; the ordinary dose for women should be five grains and for men seven and a half grains. (2) The sleep after taking veronal usually appears after half an hour, and lasts from six to nine hours; its character is the same as normal sleep. (3) High temperature, dyspnœa and pain diminish the hynotic influence of veronal. (4) The most important field for veronal is in functional nervous disturbances, and in the insomnia of pregnancy; after using the drug for a week it is advisable to discontinue it for some days as the organism rapidly becomes habituated to its use. (5) Complications seldom follow its use; at most a little dizziness or headache may occur, but neither are of long duration. M.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

Courier.—We have no particular desire to cross swords with Mr. A. A., though ready enough to do so, if occasion requires. In the present instance the challenge is too clumsy and the trap too obvious. If no notice is taken of the document mentioned, it will probably fall flat. If it be commented on it would give it a chance of additional notice. How can one argue effectively on such subjects with people who do not know the rudiments of chemistry?

Sybarite.—We are much interested in the legal anomaly that you point out to us. The point is new, and we will make careful search for information as to the fact. If it turns out that what you believe is true, the matter ought to be dealt with, and cannot be known too widely. At the same time we doubt if it is quite a subject for a medical journal, unless a medical man were directly involved in the injustice. And that, we take it, is not the case.

THE BABU AND THE DOCTOR.

Babu letters, it is to be feared, are, as a rule, either fictitious or considerably edited and embellished. The following one from Assam is as authentic as it is diverting. It is an application from a native to the steamer agent at Dibrugarh (Assam):—

"Respectfully showeth that your humble practitioner is poor man in agricultural behaviour, and much depends on season for the staff of life, therefore he falls upon his family's bended knees and implores of his merciful consideration for a damnable miserable like your honour's humble petitioner. That your humble petitioner was too poorly during last rains and was trying vernacular medicine without effectuality, but was resuscitated by much medicine of Dr. J. Lazarus, which made magnificent excavations in the coffers of your humble servant. That your petitioner has a large family of seven lives, two males and five females, last of whom is milking the paternal mother and is very noiseful, through pulmonary catastrophe in the interior abdomen. That your humble petitioner prays that if there is a place ever so small in your honour's benevolence, this slave will be allowed to creep in. For this act of kindness shall, as in duty ever bound, pray for your honour's longevity and procreativeness."—*London Opinion.*

Hants.—Many thanks for your suggestive letter. The subject was carefully gone into by us a short time ago, and we came to the conclusion that it was better to bear the ills we have than to fly to others that we know not of.

Congress.—The observations on the effect of alcohol on animal life on which you wish for information were made by H. E. Zingler and H. Fühner. They showed that one per cent. of alcohol (ethyl alcohol) added to water in which the embryos of sea-urchins were placed retarded their development. A two per cent. solution not only greatly arrested development, but tended to produce monstrosities, while a four per cent. solution markedly retarded all development.

Demograph.—The word demography is not perhaps a very happy one, and a good many people, we fancy, like you do not grasp its full signification. It does not mean, as was suggested at a congress, "teaching people to write," but is the name of the science dealing with the statistical estimation of populations and such of their conditions as lend themselves to enumeration.

HEATING FOR HEATING'S SAKE.

Business was bad in the Farringdon Road owing to the weather, and a professor selling an invaluable specific had for audience only two very small boys and a hungry-looking tramp. "Now, gentlemen," said the professor, fixing his eye on the tramp, "I don't want you to believe that this 'ere invaluable medicine works miracles. No; you 'as to consider your eatin' and drinkin'. Wot does the 'ighest medical authorities sy? Eatin' from 'abit, they sy, is a prolific cause of hindigestion. You should only heat when you wants to heat." "Oo are you gettin' at?" remarked the tramp indignantly. "I can't eat when I wants to eat, that's wot's wrong with me. And as for drinkin'—gor blimey!"—*Weekly Times of Edinburgh.*

Furuncle.—We are not prepared to recommend the treatment of boils by zinc sulphate baths, as we have no experience of it ourselves, but the details of the treatment are as follows:—Into a large bath an ounce of zinc sulphate is put, making a solution of about 1-1,000. In the usual way no irritation of the skin is caused, but if by idiosyncrasy of the patient there be any, half an ounce should be used subsequently. The baths should be taken three times a week for half an hour at a time. The skin should be rubbed with a rubber sponge after the bath. There is no reason why soap should not be used, except that it does not lather well with the solution.

Scholar.—The question of disinfecting schools was dealt with in a paper at the International Congress of School Hygiene lately held in London. You will find the matter treated there at some length. Some school authorities regularly disinfect their schools. This is certainly the case at Nottingham, Durham, Middlesex, Leeds, Birmingham, Willesden, Dundee, West Ham, and East Riding.

Vacancies.

Dorset County Hospital, Dorchester.—House Surgeon, to reside and board in the Hospital. Salary, £100. Applications to the Chairman of the Committee.

Norwich City Asylum, Hellesdon-next-Norwich.—Resident Medical Superintendent. Salary, £400 per annum, with furnished residence, fuel, light, rates, washing, etc. Applications to Arnold H. Miller, Town Clerk, Guildhall, Norwich.

Jersey Dispensary.—Resident Medical Officer. Salary, £120 per annum, furnished quarters, and attendance. Applications to Secretary.

Farringdon General Dispensary, 17 Bartlett's Buildings, Holborn Circus, E.C.—Resident Medical Officer. Salary, £120 per annum, with apartments, coals, gas, and attendance. Applications to the Honorary Secretary.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C.—Senior House Surgeon. Salary, £100 a year, with board and residence in the Hospital. Applications to the Secretary.

Newcastle-upon-Tyne City Hospital for Infectious Diseases.—Resident Medical Assistant. Salary, £104 per annum, with board and lodging, etc. Applications to the Medical Officer of Health, Health Department, Town Hall, Newcastle-upon-Tyne.

Birmingham General Hospital.—Receiving-Room Officers. Salary, £160 per annum. Applications to Howard J. Collins, House Governor.

Tunbridge Wells General Hospital.—House Surgeon. Salary, £100 per annum, with board, furnished apartments in the Hospital, gas, firing, and attendance. Applications to the Secretary.

University of Durham College of Medicine, Newcastle-upon-Tyne.—Demonstrator of Physiology. Salary, £200 per annum. Applications to Prof. Howden, Secretary of the University of Durham College of Medicine, Newcastle-upon-Tyne.

Gravesend Hospital.—House Surgeon. Salary, £100 per annum, with board and residence. Applications to A. E. Thomas, Secretary.

London Temperance Hospital, Hampstead Road, N.W.—Resident Medical Officer. Salary, £120 per annum, with board, lodging, and washing. Applications to A. W. Bodger, Secretary.

Salford Union.—Resident Medical Officer. Salary, £130 per annum, with furnished apartments and attendance in the Infirmary. Applications to F. Townson, Clerk to the Guardians, Union Offices, Eccles New Road, Salford.

Durham University College of Medicine.—Demonstrator of Physiology. Salary, £200 per annum. Applications to Professor Howden, Durham College of Medicine, Newcastle-upon-Tyne. (See advt.)

Appointments.

McWalter, J. C., M.D.Brux., M.A., F.F.P.S.Glasg., D.P.H., Barrister-at-law, Examiner in Medical Jurisprudence to the Apothecaries' Hall of Ireland.

Palmer, F. W. Morton, M.B., B.C.Cantab., Ophthalmic Surgeon to the Teignmouth Hospital.

Phippen, Harry G., M.R.C.S.Eng., L.R.C.P.Lond., Assistant Medical Officer at the Western Hospital, Fulham, London, S.W.

Births.

Macevoy.—On Sept. 11th, at 41, Buckley Road, Brondesbury, London, the wife of H. J. Macevoy, M.D., B.Sc.Lond., of a son

McClintock.—On Sept. 12th, at The Chestnuts, Loddon, Norfolk, the wife of Lawson Tait McClintock, M.B., of a daughter.

Marriages.

Iles—Pink.—On Sept. 12th, at St. Barnabas', Bexhill, Alfred John Hopkinson Iles, M.R.C.S., L.R.C.P., son of Alfred Robert Iles, M.R.C.S., L.R.C.P., of Taunton, to Florence Mabel, elder daughter of Edward Pink, of 5 Gwendolen Avenue, Putney.

Rose—Waller.—On Sept. 14, at Emmanuel Church, West Hampstead, William David Rose, M.B.C.M., of Luton, to Mabel, daughter of Charles Ashton Waller, Long Compton Manor, Warwickshire.

Deaths.

Crowfoot.—On Sept. 11th, at Beccles, Suffolk, William Bayly Crowfoot, M.A., M.B., B.C.Cambridge, aged 29.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, SEPT. 25, 1907. No. 13

NOTES AND COMMENTS.

Examinations for Wives.

WITH all the talk there has been, and rightly been, about maternal ignorance and its lamentable consequences, there has risen a desire that mothers—actual and potential—should be educated in the duties of housewifery and motherhood. No doubt, if the instruction be as good as the intention, such classes will do much to prevent women falling into the mistake of giving children whatever they cry for, or even a "bit of what we 'as oursel's," and they cannot but help in the promotion of a sense of responsibility on the part of mothers towards their children, and thus tend to preserve the physical and moral welfare of the race. Now, the logical corollary to instruction is examination, and there can be no harm in testing the aptitudes of pupils to retain the knowledge that has been imparted in these classes, but we confess to being somewhat staggered at the proposal made in a contemporary that there should be an examination for women before they became wives. The examination craze has reached heights of imbecility which its most ardent initiators could hardly have dreamed of, but if the maidens of Great Britain have to pass an examination before they can become eligible for the honour of a man's hand, we fancy we should range ourselves on the side of the angels and oppose the plan with all possible vigour. The plain fact is that the prettiest girls are notoriously the stupidest, and if none but the ugly girls could get married, whatever result their ability might have on the nature of the infant, it would not take long before there were no types of British beauty left to lighten the burden of a drab world.

Chops v. Logic.

SIR JAMES CRICHTON-BROWNE'S presidential address to the Sanitary Inspector's Association, in which he praised the virtues of a substantial meat dietary, has brought about his ears the clamours of all the food faddists and self-advertising folk who enjoy the notoriety attending free contributions to the September newspapers. It is a curious comment on the influence gained by such folk on the mind of the public that it should be necessary for a well-known medical man to utter such a platitude as that mutton-chops and roast beef are good things to eat, and, still more so, that it should excite any attention in a nation whose boast has always been that beef and beer have built up an empire against which the eaters of sauerkrout, horse-sausage, and frogs' legs rage impotently. In the days before people took to analysing their sensations so minutely, and took more exercise in the open air, beef and beer established their reputation as a dietary by the exceedingly comfortable feelings they produced when taken by tired and healthy people. If it has come to this, that there really are a large number of folk in this country who actually cannot get their ordinary wants supplied by beef and mutton, but find satisfaction only in the cauliflower and lettuce, then we can only deplore the loss of national vigour which such anæmic taste connotes. Indeed, did the vegetarian realise it, he should hide his habits in the corner, for to confess them is to write himself down a subnormal person, and while, we take it, he would not boast of an asymmetry of his face, a high arch to his palate, or any of the stigmata of degeneration, he delights to parade in public the ineffectiveness of his gall-bladder and pancreas.

Southend v. Dr. Nash.

THE Southend Town Council, after a due period of reflection, have made their choice, and decided to give up their medical officer of health, Dr. Nash. The battle is one of great moment, and the issues cannot be too clearly laid before the profession. Dr. Nash was appointed Medical Officer of Health to the Council in 1901 at a salary of £400 a year, the agreement being for three years. In 1904 he was duly re-appointed at £500 a year, and the period of his appointment at that rate expired this summer. The Health Committee proposed his re-appointment at £650, the extra hundred being the normal triennial advance, and the extra fifty being payment for work for the Education Committee. However, when the matter came before the full Council, it was proposed and carried that he should be offered the appointment but for one year, and that the salary should be only £500. Now, this opposition to the Health Committee's recommendation was not dictated by any simple desire for economy, or any suggestion that Dr. Nash had been remiss in his duties. It was, in fact, due to the precise opposite, namely, that Dr. Nash had been too energetic and thorough, and had thereby brought himself into conflict with certain interests of the town. In a question extending over several years it is not possible or wise to apportion blame exactly, but whereas the Health Committee, which may be supposed to know the real merits of Dr. Nash's administration better than anyone, strongly supported him, certain members of the Council were actuated by a spirit of hostility. Dr. Nash refused to accept the rebuff, and would have resigned immediately, but for being persuaded to continue temporarily with a view to the matter being thoroughly thought out.

No "Blacklegs."

THE Council then prepared advertisements for insertion in the medical press, but they found themselves faced with the difficulty that the medical press would not accept the advertisement. Moreover, the medical practitioners of the town, many of whom did not see eye to eye with Dr. Nash, unanimously condemned the action of the Council. Only one man, and he, presumably, unsuitable, came forward to apply for the post, and the Council consequently found themselves in a quandary. Accordingly, on the 17th, another meeting—a long and stormy one—was held, and the Health Committee's recommendation that Dr. Nash be appointed at the increased salary was thoroughly considered. This time the force of the opposition was disclosed, the charges being then made that Dr. Nash had brought the sanitary dangers of Southend too much to the fore, and thereby got the town a bad name. Eventually the increased salary was refused by a majority of one vote, and Dr. Nash's temporary occupancy of his post will consequently expire in a month or two's time. We strongly add our advice to that already given that Dr. Nash be supported in his protest, and that no medical man apply for the post. To do so would be to stultify the effect of the action taken, and to postpone the operation of the urgently-needed principle that a medical officer of health may set himself to remedy wrong without fear or favour. If Southend cannot get a medical officer, the Town Council will be brought to their senses in the most effectual and practical way.

Medical Boycott of Duelling. A curious ethical point has arisen in Sicily by the refusal of the medical practitioners of Palermo to attend duels. The profession of that island, being more civilised than their lay colleagues, see the criminal absurdity of "affairs of honour," by means of which an expert swordsman is at liberty to bully any ordinary folk with impunity, or to have the pleasure of spitting them with his sword if they have enough spirit to resent his insults. This boycott has given rise to a variety of opinions among French medical men who have been interviewed by the *Liberté*. There are those who hold the doctors justified in their action, and there are others who consider that the function of a medical man is to relieve suffering, and that he has no concern with the causes of the dispute by which the suffering was incurred. Now, while it is true it is the doctor's function to patch up a burglar whom he has shot while breaking into his house, it is straining the medical ideal very far to say that medical men are not justified in making a collective, practical protest against a barbarous custom which could not go on but for their connivance. We take it that none would refuse to dress a wounded duellist who was brought to their surgeries, but it certainly is below the dignity of civilised gentlemen to sneak about dodging the police to reach the duelling field in order to assure the minimum of danger to quarrelsome people who seek the arbitrament of the sword. In our opinion, the Palmero doctors are not only justified in their action, but they are playing an enlightened *rôle*, and one which does them much credit. Almost any action would be justified if it succeeded in putting an end to such a ridiculous anachronism as duelling.

LEADING ARTICLE.

A SUPREME NATIONAL HEALTH AUTHORITY.

The proposal to unite the chief local sanitary authorities of the United Kingdom by the common bond of a Central Representative Union is so obviously sound as to deserve close attention on the part of all who may be directly or indirectly concerned. It has emanated from Dr. H. E Armstrong, the well-known Medical Officer of Health for Newcastle-upon-Tyne, at which place an executive committee has been formed. After due consideration, it has been decided to hold a preliminary conference in London of the representatives of the sanitary committees of the county councils, county boroughs and municipal boroughs (metropolitan and provincial) and port sanitary authorities of England and Wales. At this stage of the proceedings it is felt that it would be unadvisable to include all the local sanitary bodies in the United Kingdom, owing to their great number. The circular letter which has been sent out to the chairmen of the invited committees, however, expressly states that every Authority in the Kingdom should be duly represented on the National Authority it is now proposed to constitute. The germ of the movement is contained in the distinction thus drawn between the local and the national handling of questions concerning the public health. Under present conditions local administration is more or less chaotic; nor, in the absence of common standards of comparison and of methods of exchanging views and experiences, and of formulating model codes, can this developmental incompetence be a matter of wonder. It is pointed out in the Newcastle circular that the absence of conformity of action on the part of sanitary authorities generally has been recognised for a long time past, and, on account of the diversity of interests involved, has hitherto been regarded as a matter of almost insurmountable difficulty, as well as a cause of much waste of energy and time in attempting to carry out broad measures of sanitary reform. This difficulty Dr. Armstrong and his supporters hope to overcome by starting a kind of sanitary parliament, to act as a central body and to consist of representatives of every sanitary authority in the United Kingdom. The function of this body would presumably be to draw up responsible recommendations which would be available for the legislature on the one hand, and for local administrations on the other. As the Newcastle Committee remarks, the necessity for such an organisation has been experienced by most of the sanitary authorities of the Kingdom. The movement to provide it has been rightly interpreted as the result of a desire to bring into existence a body which will focus the opinion of all engaged in public health work, and make their experience effective in requiring legislation to promote the object in view. Perhaps the greatest function so far allotted to the proposed union is that of advising the legislature. It is obvious that sanitary authorities, from their daily experience of the working of Public Health Acts, must be familiar with legal shortcomings, just as they must necessarily be the best judges of sanitary defects that are not met by existing legislation. To a great extent a competent central union would be able to frame practical measures for meeting national issues of such tremendous importance and complexity as infant mortality, the pollution of rivers, tuberculosis in man and animals, and the meat and milk supplies. A great public discussion, say, on the housing problem by an assembly of informed debaters could not fail to bring home to the nation with irresistible force the wrongs inflicted upon the community by the jerry builders and the privileged landlord. The impulse to Parliament to pass new building Acts would be of a nature unlike anything at present in existence. Similarly, it is unlikely that after a few years of persistent exposure by the Union of the evils of contaminated drinking-water supplies that Londoners would contentedly continue to drink water drawn from a river extensively polluted by sewage. There is no need to multiply instances. The field is a large one, the workers are earnest and multitudinous, but the problem is to render them articulate and to bring them into touch so that their individual experiences may be crystallised into general propositions of value and authority. The whole scheme, if properly carried out, bids fair to mark one of the most important departures ever yet made in the public health history of the United Kingdom. The first conference, it is announced, will be held in London between November 12th and 15th next. As the future of the movement will largely depend on its reception at the first meeting, we trust that all the local sanitary bodies that have been approached will make an effort to be represented at the preliminary conference in November.

POOR-LAW MEDICAL.

THE recent resignation of the whole of the medical staff of the Fir Vale Union Infirmary, at Sheffield, opens up a subject that has for some time past been in need of revision. With the immediate cause of the resignations we are not here concerned. It suffices for present purposes to know that the conditions of professional work at the Poor-law institution in question have been such that five medical men have taken the serious step of throwing up their posts. Those who have had any extended experience of such positions know that in the majority of cases friction arises from an unwarranted assumption of authority on the part of the lay officials of the institution concerned. In these cases the lay officers are often permanent, while the resident medical officers are young men who have a limited tenure of office. From the necessities of the position, therefore, the guardians are naturally more likely to favour those whom they have known for the longer period of time. Apart from that particular phase there are other and deeper principles involved. One of the foremost of these is the proposition that in a sick infirmary medical control should be permanent. If it were so the public would be spared many of the scandals arising directly out of understaffing in Poor-law infirmaries; scandals which are now only too frequent. The Sheffield case is not sufficiently ripe for discussion. At the same time, it will be well to point out one serious error that has crept into the lay newspapers, namely, the statement that the resignations have been prompted by the local branch of the British Medical Association. As a matter of fact, the question has not yet been considered by that body. In view of the importance to the medical profession of the readjustment of the present unsatisfactory conditions, it is to be hoped that the matter will not be allowed to drop until is has been threshed out between the guardians, the Local Government Board, and the medical profession in Sheffield. We hope to keep our readers fully informed of the course of events.

CURRENT TOPICS.

Poison Epidemic in Essex.

AN outbreak of fortunately mild ptomaine poisoning occurred recently in several Essex villages near Colchester. About fifty persons were attacked, but all recovered within a few days, and the epidemic was ultimately traced to some infected brawn. The incident is one of a far too familiar type, but it is difficult to see how accidents of a similar kind can be altogether prevented. Even in the case of careful and conscientious tradesmen, carrying on their work in a cleanly environment, it is quite possible occasionally to overlook the tainting of so perishable an article as butcher's meat. There is the further fact that meat may be capable of causing disastrous illness, although it bears little or no evidence of the danger by signs appreciable to the senses of sight, smell and taste. The only scientific way that suggests itself of preventing the possibility of contamination would be to have food prepared with aseptic precautions, and stored in a sterile environment, with directions to be consumed within a certain number of hours. In human affairs, however, the counsels of perfection will always have to be modified by the requirements of daily life. Incidentally, in the Essex epidemic, a dog which had stolen some of the incriminated brawn was reported to have suffered severely. This incident, while it afforded valuable evidence to the sanitary authorities, has, at the same time, furnished a somewhat knotty problem for the moralist. In this case Providence seems to have punished alike the guilty dog and his innocent owners, although the one stole his brawn, and the other bought and paid for it.

Germany and Patent Medicines.

THE German legislature usually takes a short cut in dealing with offenders against the public weal. Since 1903 it has completely altered the conditions of the patent medicine trade by compelling the makers to state on each packet or bottle the ingredients and their quantities. Now it has gone a step further and adopted a further plan that bids fair to kill the most noxious of all trades. From October 1st next all written or printed praise of the specific is forbidden, and all public advertisement. No chemist, moreover, who does not know what a patent medicine is made of may supply it without a doctor's order. Why should not a similar law be passed in the United Kingdom? The evil wrought upon the health of the community by the sale of patent medicines is incalculable. The medical man who is scientifically trained in the remedial treatment of disease has no secrets. Why, then, should the ignorant charlatan be permitted to claim for alleged specifics the power of curing manifold maladies? The transaction is, in plain words, a fraudulent attempt to procure money under false pretences. The growing intelligence of the community must one day put an end to a trade that is carried on at the cost of untold injury to the health of the people. What is possible in Germany is surely possible in our own country.

Maternity Homes and Syphilis.

THE recent appearance in a police court of the matron of a maternity home suggests various questions of medical general interest. The institution in question was called a school of midwifery, and one of the witnesses produced a certificate stating she had undergone a course of instruction there, and was qualified to act as a monthly nurse. It will be interesting to learn what control the Central

Midwives' Board had over the institution as regards the quality and the quantity of the teaching. Another point arises out of the evidence of a police surgeon to the effect that a child was suffering from hereditary syphilis of a bad form. In his opinion the condition of the child might have been alleviated by medical attention. So far as can be gathered, there appears to have been no systematic medical treatment attempted. Apart from the merits of this particular case, however, it is of considerable interest to enquire whether the neglect to treat an infant suffering from constitutional syphilis might be legally construed into an act of criminal neglect. A maternity home might reasonably be supposed to have the experience necessary for the recognition of such a malady. It would be obviously a first duty to instruct midwives upon the chief facts of syphilis, both in mothers and in infants. The obligation to provide medical attention probably applies to institutions as it does to other responsible guardians, and not less so in syphilis than in other diseases.

Edible Fungi.

THE recent lamentable occurrence at Ipswich whereby a whole family was poisoned by eating fungi has led to enquiry as to how edible mushrooms may be distinguished. Now, there are two kinds of mushroom. First, the common mushroom (Agaricus campestris), which has a white stem and cap. Underneath the head are a number of gill plates radiating from, but not attached to, the stalk. They are pink in colour, and form the under lining of the head. In the developed mushroom an annulus is found round the stem. In the earlier stages of growth, when the mushroom resembles a solid white button, the annulus is attached to the white covering of the cap or pileus. The colour of the fungus darkens with age. The second kind of mushroom is the Agaricus arvensis. It is also called the meadow mushroom and the horse mushroom. It is the larger of the two, the gills below the cap are whitish instead of pink, and with age they become very dark. It is not as good as the common mushroom for making ketchup, and still less for eating purposes. While the most of people eat mushrooms with relish and impunity, there are others who are liable to attacks of sickness from their use. On the gills of fungi the spores are to be found, and these spores show whether a particular fungus is to be regarded with suspicion or not. Mr. M. C. Cooke, in "British Edible Fungi," describes how the spores of a fungus should be examined. The fungus should be placed on a sheet of paper, with the gills downward, for a few hours or over-night. When removed, a very fine dust is observed to have been thrown down on the paper from the gills. This deposit is either white, salmon-coloured, brown or tawny, dark brown or black. In the common mushroom the spores are of a dark purple-brown. A great number of species which have purple-brown spores are edible, whilst it is very rare indeed for a species with salmon-coloured spores to be worth eating, and some are poisonous. The colour of the gills and of the spores are of considerable importance, and must be taken into account in determining a fungus. Mushrooms ought to be cleaned before being eaten, and rejected if any parasites are found on them.

A Source of Tuberculosis in Pigs.

Now that the identity of tuberculosis in man and in the lower animals is established, we are likely to be faced with many fresh precautions arising logically out of that far-reaching law. An instance in point came recently from a northern town, where the guardians have adopted an attitude that might well be taken as a pattern by all Poor-law authorities called upon to deal with the problem of tuberculosis. A medical man pointed out to his fellow guardians that all waste food collected in the phthisis ward of the local union hospital was placed in the swill-tub, and afterwards sold for the purpose of feeding pigs. The risk of spreading tuberculosis, first amongst pigs, and, secondarily, amongst the consumers of the diseased flesh, is obvious. Of all the lower animals, the pig is one of the most susceptible to invasion by the bacillus tuberculosis. We are pleased to say that the guardians immediately resolved that in future all the waste food from the ward in question should be burned. The matter is deserving of the widest publicity, as it is only by attention to details of this kind that the "white scourge"—as it is sometimes aptly termed—will be one day eradicated. There are many points in connection with waste food to which the attention not only of the public, but also of medical men and nurses, might be drawn with advantage.

The Lord Mayor and the Cripples' Homes.

THE scheme which the Lord Mayor has done so much to promote—namely, the establishment of an institution for cripples, partly hospital and partly educational home, has been greatly helped forward by the gift from the War Office of the Princess Louise Military Hospital at Alton. The value of this property runs to many thousands of pounds, and we believe that such a presentation from a Government to a body of eleemosynary trustees, without consideration, is the first of its kind in this country. As the Lord Mayor has received £50,000 in donations wherewith to start his home, and £60,000 is all that is needed to put it on a firm financial basis, it may be presumed that the success of the institution is assured. It is certainly difficult to see how without this gift Sir William Treloar would have been able to have carried through his scheme in anything like an adequate manner, and now accommodation for only a hundred and fifty will be forthcoming. Yet we seem to remember the statement being made some time ago that £60,000 would relieve all the crippled children in London. While thoroughly recognising the Lord Mayor's kindness of heart in seeking to provide still further for the cripples, it must be hoped that his spirited efforts have not drawn away support from the excellent institutions at present in existence, many of which find it very difficult to keep up their subscriptions-list as it is. Whilst wishing every possible success to the new home, may we express the hope that the committee will place themselves under trustworthy medical guidance as regards the treatment of the children, and eschew the blandishments of interested quacks?

Consumption and Breach of Promise of Marriage.

WE do not know that the fact of a person's suffering from consumption has ever been put forward in this country as a justification for breach of promise of marriage by the other party. In the Supreme Court of Washington, however, a decision has just been given in which the case rested on this plea. It appears that the engagement had been entered into by the man with the knowledge that the woman suffered from consumption. He afterwards broke the engagement on that ground, and the Supreme Court held that he was justified in so doing. There are doubtless good reasons why a woman suffering from phthisis should not marry, but we can hardly understand how a contract can be justifiably broken on account of facts known at the time the contract was entered into. It is more than doubtful whether such a plea would be upheld in this country, but in America there is a much greater tendency to limit the freedom of the diseased or degenerate individual to propagate his kind.

Consumption in the Hebrew Race.

The comparative immunity of the Hebrew race from consumption has always been regarded as one of the facts of racial natural history. That belief, however, has been somewhat rudely shaken by Dr. S. A. Jacob, a non-medical philanthropist, who was until lately President of the Consumptive Aid Association in Leeds. That position he has now resigned in order to devote himself entirely to the formation of a Jewish branch of the Tuberculosis Association. This step was prompted by the rapid increase of consumption amongst his co-religionists. Dr. Jacob has given a powerful description of the miserable houses of the local Hebrew population amongst which the cases are found. It may be gathered that he refers to slum districts peopled by poverty-stricken alien Jews from Russia, Poland and other parts of the Continent, who have of late years invaded the great towns of the United Kingdom. There is, of course, no absolute racial insurance of the Jews against tuberculosis. Given the conditions of bad air, poor feeding, overcrowding, and an unfavourable slum environment, and the Hebrew will contract the disease as easily as the Christian. We presume that Dr. Jacob is alive to the probability that slum tuberculosis is to a certain extent due to infected milk and flesh. Although incapable of exact proof, that is the inference most likely to be adopted by the educated medical man, in view of the recent authoritative finding of the Tuberculosis Commission as to the identity of the malady in man and the lower animals.

Smoke and Disease.

There is little doubt that the constant breathing of smoky, soot-laden air is injurious in some degree to the lungs. Probably the irritation caused by particles of soot is one of the most important predisposing causes of tuberculosis, and it has been shown by experiment that guinea-pigs which had lived in a smoke-laden atmosphere died of pulmonary tuberculosis more quickly than those which showed smoke-free lungs. It is, of course, notorious that people already afflicted with phthisis thrive better in a pure than in a smoky air. Notwithstanding all this, but little support has been given by the medical profession to the movement for the abolition of the smoke nuisance. It is true that in many of the English cities there are by-laws controlling the issue of black smoke, but the problem as a whole has, as yet, hardly been touched. Possibly in the long run the solution will be found in the substitution of coal-gas for coal for manufacturing purposes, as has been done on a limited scale in South Staffordshire and some other districts. It has been found possible there to produce at cheap rates a gas very suitable for manufacturing purposes, though useless as an illuminant.

PERSONAL.

Queen Wilhelmina and Prince Henry were present at the opening of the International Congress of Psychiatry and Psychology held at Amsterdam at the beginning of this month.

The Annual Presidential address of the West London Medico-Chirurgical Society will be given on October 4th at 8.30 at the West London Hospital, the subject being "The Relationship of Disease of the Ear, Nose, and Larynx to General Medicine." The new President is Mr. Richard Lake.

It is announced that Dr. H. P. Motteram has been nominated for the Mayoralty of Smethwick.

Dr. C. T. Wright, Professor of Midwifery at Leeds University, has resigned his office after forty years' service in connection with the Leeds Medical School.

The Royal Dental Hospital of London, Leicester Square, has received £250, less legacy duty, from the Executors of the will of the late John Lawrence Toole, Esq.

Dr. George Newman has resigned his post of Medical Officer to the Finsbury Borough Council, on his appointment as Chief Medical Officer to the Board of Education.

Professor Francis Gotch, M.A., D.Sc., F.R.S., will present the prizes awarded by the Faculty of Medicine in the large hall of University College, Bristol, on October 1st.

The Order of the Hospital of St. John of Jerusalem in England has been conferred on Dr. Arthur J. Evans, of Liverpool, for his services to the wounded at the earthquake in Jamaica.

The Second Norman Kerr Lecture of the Society for the Study of Inebriety will be delivered by Dr. Robert Welsh Branthwaite, on Tuesday, October 8th, at 20, Hanover Square, London, W.

The Inaugural Address of the Winter Session of the London School of Clinical Medicine will be delivered by Sir Richard Douglas Powell, Bart., K.C.V.O., M.D., on Tuesday, October 8th.

First-Class Hospital Assistant P. S. Ramachandrier, of the Mysore Medical Service, has been awarded the prize offered by the *Indian Medical Gazette* for the best essay on the prevention of plague.

Sir Arthur Conan Doyle was married very quietly on September 18th at St. Margaret's Church, Westminster, to Miss Jean Leckie, daughter of Mr. and Mrs. James B. Leckie, of Glebe House, Blackheath.

At Friday's session of the International Tuberculosis Conference, Dr. Klemens Pirquet presented an interesting report on his experiments in the inoculation of infants with tuberculin in order to detect the presence of tuberculous germs.

A Clinical Lecture
ON
CONGENITAL ANOMALIES OF THE EYE. (a)

By SYDNEY STEPHENSON, M.B., F.R.C.S.Ed.,

Ophthalmic Surgeon to the Kensington General Hospital, the Evelina Hospital, the North-Eastern Hospital for Children, etc.

The expression "congenital anomalies of the eye" chosen by the Reader in Ophthalmology for the title of this lecture, is in itself somewhat anomalous—at least, without further definition. As generally applied, however, it means some malformation in structure or some anomaly in function present when a baby is born, or (much more rarely) arising soon after birth, as in the curious condition known as "opaque nerve-fibres of the retina." In short, it is usually a birth anomaly—that is, an inherited as distinguished from an acquired defect. We must carefully exclude those defects, as corneal opacities, paralysis of the ocular muscles, irido-dialysis, ptosis, ectropion, and so forth, which are liable to result during the progress of birth by the use of instruments and otherwise.

There is perhaps no part of the human body whose congenital anomalies are more numerous and important than those of the eye and its appendages. This is doubtless connected with the extremely complex structure of the eyeball. The readiness with which practically every part of the eye can be examined, too, has led to the discovery of many defects that would probably have escaped attention in any other organ of the body.

Many of the so-called congenital anomalies of the eye, however, are of interest merely from the embryological point of view, but others, such as infantile glaucoma, microphthalmia, cryptophthalmia, and coloboma of the choroid, may result in such defective sight as to render them matters of importance to the practising surgeon. In this event such malformations may rightly be looked upon as "congenital diseases" if only for the purpose of distinguishing them from the others, which may be called "congenital defects."

At the outset we are constrained to confess our essential ignorance of the causation of many congenital anomalies of the eye. Certain of them, particularly perhaps the conditions known as opaque nerve-fibres and ectropion of the uveal layer of the iris, appear to represent a reversion to a type found in the lower animals, and a similar explanation, as will be explained later, has been applied by Mr. E. Treacher Collins to account for cases of infantile glaucoma. In other words, these are examples of atavism. Many anomalies may be accounted for by delay, failure, or perversion of the normal processes of development. This factor adequately explains many of the deformities, among which may be mentioned persistent pupillary membrane and hyaloid artery, and, in particular, coloboma of the choroid downwards. At the same time it is inadequate to account for some others, such as coloboma of the eyelids, cryptophthalmia, and congenital staphyloma.

Two alternative explanations have been offered for some of these cases:—(1) an inflammation of the tissues of the eye during the sojourn of the fœtus in its mother's womb; and (2) the influence of adhesions between the amnion, on the one hand, and the integument of the fœtus, on the other.

(1) The theory of intra-uterine inflammation (closely connected with Deutschmann's name) is capable of explaining certain malformations, as congenital leucoma and staphyloma, which it is difficult or impossible to account for on developmental grounds.

(2) Adhesions are known to be liable to occur when the quantity of amniotic fluid is unusually scanty, as in cases of oligo-hydramnios. But many such adhesions are now believed to be the cause of spontaneous amputation, of encephalocele, and of fissures of the face, lips, or jaw. Coloboma of the eyelids could be satisfactorily accounted for on the adhesion theory, as could also a singular congenital condition described by Schapringer as "epitarsus," in which adventitious folds of conjunctiva exist upon the inner surface of the upper eyelid.

It is impossible that more than one of the foregoing factors may come into play in the production of certain malformations. Thus, an arrest of or perversion in development may be the direct or indirect outcome of an intra-uterine inflammation, and so forth.

Another point is that our knowledge of the development of the human fœtus is still incomplete. It may accordingly be assumed that some anomalies that cannot at present be explained on developmental grounds may yet be accounted for in that way when we comprehend more completely the processes of development, normal and abnormal, as we some day shall surely do. This suggestion is exemplified by the modern explanation of so-called "central coloboma of the choroid," *i.e.*, a more or less circular defect in the choroid occasionally met with in the neighbourhood of the macula lutea. It is difficult to account for this defect as connected in any way with the fœtal ocular cleft, which, as will be explained in detail later on, develops early in fœtal life and is directed downward. In order to meet this anatomical stumbling-block, the ingenious but unconvincing hypothesis was propounded that the eye rotated 90 deg. during its development. The explanation of the anomaly appears to lie, however, in the occasional existence of a subsidiary fœtal cleft, of which examples have been seen in some of the lower animals, as the sheep, the chicken, and the calf.

Other factors that can scarcely remain without influence in the causation of anomalies of the eye, as of other parts of the body, are syphilis, diseases of the placenta, or fœtal membranes, and general conditions, such as tuberculosis and alcoholism, in the parents.

As to the influence, if any, played by "maternal impressions" in determining congenital anomalies, we remain in complete ignorance.

The transmission of certain eye defects, such as irideremia and ptosis, opens up large and complex questions, not peculiar to ophthalmic work, upon which no consensus of opinion has yet been reached.

Before describing some of the more important abnormalities, something should be said in outline as to the development of the eye, perhaps the only subject connected with the eye not yet discussed in the post-graduate course of ophthalmology provided by the University of Oxford.

Development of the Eye.

At a very early stage in fœtal life, at a time when the nervous system is represented merely by a narrow tube provided at one end with certain dilatations known as the three primary brain vesicles, the rudiment of the eyes appears as a hollow bud, called the primary optic vesicle, arising from each side of the anterior primary cerebral vesicle. The hollow connection between the two vesicles, ocular and cerebral, becomes narrowed, is occupied by vascularised mesoblastic tissue, and is eventually differentiated into the optic nerve.

The primitive ocular vesicle, in common with the rest of the embryo, is covered with a layer of closely-packed cells, the epiblast. Enclosed within the epiblast lie the so-called mesoblastic cells. The hypoblast takes no share in the formation of the eye.

Now the cells of the epiblast at a point corresponding to the optic vesicle, become both thickened and more numerous, so that several layers of embryonic cells are closely packed together at that point. This collection of cells represents the rudiment of the crystalline lens. The primary ocular vesicle lying contiguous to the lens rudiment becomes pushed back, like the finger of a glove, in such a way as to produce a pouch, of which the closed end is directed towards the vesicle. This, which is known as the secondary ocular vesicle, is merely the primary ocular vesicle folded upon itself—invaginated, as it were—and like the latter, is composed of epiblastic cells. Simultaneously with these changes, the collection of epiblastic surface cells becomes separated from the superficial epiblast, and at last lies quite apart from the last-named. The surface epiblast grows over the detached group of cells, the edges of which cohere, so as to form a closed sac, known as the lens sac or vesicle. At a later period of development this sac becomes converted into a solid body, the crystalline lens, by the continued growth of its component epiblastic cells.

(a) A Clinical Lecture delivered July 19th, 1907, in the Post-Graduate Course of Ophthalmology in the University of Oxford.

While these changes are going on, the lower aspect of the primary optic vesicle becomes invaginated by a process of mesoblast, a tissue which surrounds the optic vesicle. The optic cup is accordingly incomplete below, the hiatus being known as the fœtal ocular cleft, a structure of considerable importance from our present standpoint. In mammalia the mesoblast pushes its way through this fissure, carrying a vessel with it, so as to reach the interior of the eye, where it separates the lens rudiment from the rudiment of the retina, and eventually forms the vitreous humour. At a subsequent period (in man during the sixth or seventh week of life) the edges of the cleft unite, with the consequence that the eye again becomes a closed spherical sac. A delay in closure accounts more or less satisfactorily for coloboma of the choroid downwards.

The two layers of the secondary optic vesicle speedily commence to differentiate, so that the internal layer eventually forms the retina proper, and the external, the pigmented epithelium appertaining to that structure. The rudimentary choroid is produced from mesoblastic tissue lying outside the optic vesicle. Similar tissue also pushes its way between the outer epiblastic layer and the lens rudiment, and produces the rudiment of the cornea. The epithelium of the cornea, however, is the product of the outer epiblastic layer of cells. The sclera is a mesoblastic structure.

The fœtal lens is provided with special provision for nourishment in the shape of a vascular enveloping capsule, the tunica vasculosa lentis, the anterior portion of which is known as the pupillary membrane. This is developed as early as the second month, and, its work having been finished, should be absorbed shortly before birth. The familiar appearance known as persistent pupillary membrane is due to the survival of portions of the membrane.

The tunica vasculosa lentis obtains its blood supply from a branch of the central artery of the retina, the forerunner of which enters the eyeball through the fœtal ocular cleft along with the intruding mesoblastic tissue. The hyaloid artery, an offset from the central artery of the retina, passes through the vitreous from the optic nerve to the posterior pole of the crystalline lens, enclosed in the canal of Cloquet. Persistence of this vessel, which in rare cases may even continue to carry blood, is one of the best-known and most striking congenital anomalies of the eyeball. Traces of the anterior attachment of the hyaloid artery to the lens are, in my experience, quite common, appearing as a tiny grey opacity situated on the posterior surface of the lens somewhat to the inner side of the posterior pole. Several observers have described appearances which they considered pointed to persistence of the canal of Cloquet.

The eyelids are produced at an early period by two folds of epiblast, together with included mesoblastic tissue, growing one from above and the other from below the cornea. They are not formed, so far as we know, from several centres, as they should assuredly be if deficiencies were to be explained on developmental grounds. The rudimentary lid-folds eventually meet, and become united along their edges by proliferation of the epithelium. In man this temporary closure of the conjunctival sac begins in the third month, and undergoes retrogression a short time before birth (Hertwig), although in rare instances babies are born with a more or less complete union between the eyelids (ankyloblepharon).

The lacrymal gland is formed by budding of the epithelium of the conjunctival sac. The buds, at first solid, gradually become hollowed out. Absence of the lacrymal gland has been described, but in most instances upon somewhat slender evidence, such as the mere absence of the tears.

The lacrymo-nasal duct is formed from a solid rod or ridge of proliferated epidermic tissue, which extends from the mesial side of the eye into the nasal cavity. This solid cord becomes hollowed out by liquefaction of its contents. Should differentiation be delayed, we may have the condition of so-called "congenital dacryocystitis," which is not infrequent in newly-born children.

Congenital Anomalies.

In describing the congenital anomalies of the eye, I shall attempt a rough classification in consonance with what has already been said as to the cause of the several conditions—I. Anomalies due to arrested or perverted processes of development. II. Anomalies due to amniotic adhesions; and III. Anomalies due to intra-uterine inflammation.

I.—Anomalies due to Developmental Defects.

Defects due to developmental anomalies form the largest group. We shall describe as perhaps the most important members of this group, persistent pupillary membrane, coloboma of the iris, lens, and choroid, irideremia, opaque nerve fibres, ptosis, persistent hyaloid artery, certain developmental anomalies of the eyelids and lacrymal apparatus, and, lastly, dermoid tumours of the eyeball and elsewhere.

Persistent Pupillary Membrane.—It is not very rare to find, on an attentive examination of an eye, one or more fine strands of tissue arising from the anterior surface of the iris, near the small circle, or corona iridis, and passing to an insertion elsewhere in the corona. These are examples of persistent pupillary threads. This is one of the commonest congenital anomalies of the eye. For instance, it was present in 68 of 3,414 eyes, or in 1.99 per cent., examined by me some years ago (*Trans. Ophthalmological Society*, Vol. XIII., 1893). It is usually limited to one eye, and the anomaly is apt to reproduce itself in several members of the same family. As a much rarer condition, the filaments may be so extensive and thick as actually to interfere with sight, and it has now and then been found necessary to treat such cases surgically. As might be expected, persistent pupillary membrane is not infrequently associated with other congenital deformities of the eye, such as microphthalmia, opaque nerve fibres, congenital crescent of the optic disc, and various forms of cataract and colobomata. A rare but interesting association is with anterior synechia, as in cases reported in this country by Silcock, Treacher Collins, and Ballantyne. The distinction between persistent pupillary membrane, on the one hand, and posterior synechia, on the other, can generally be established without difficulty by careful examination of the eye. It must not be forgotten, however, as in a case figured by Fuchs (*Text-Book of Ophthalmology*, second American edition, 1899, p. 292), that the two conditions may co-exist. It has been suggested that pupillary remains are likely to disappear during the earlier years of life. Although my own figures lend no support to such a view, there is nevertheless a certain amount of direct evidence to show that absorption may occur after birth (Hirschberg).

Coloboma of the Iris.—Coloboma iridis is the name applied to a congenital cleft, often affecting both eyes, much resembling the result of a cleverly-made iridectomy. The cleft is directed downwards, although it may have a slight inclination inwards or (less commonly) outwards. It may be small, or, on the contrary, extend from the pupil to the ciliary body. It is not infrequently associated with a coloboma of the choroid. A "bridge coloboma" is a coloboma of the iris which is crossed by one or more bands of tissue pigment or pupillary membrane, as the case may be.

Coloboma of the Lens.—In this condition the crystalline lens shows a defect, almost always in the lower margin. The deficiency is generally notch-like and single, although Meyer (*Rev. Générale d'Ophtalmologie*, January, 1893) has reported a case in which a couple of gaps existed at the lower edge of the lens of one eye. In coloboma of the lens it is not uncommon to find the fibres of the suspensory ligament to be absent from an area corresponding to the deficiency in the lens. This observation is of interest, since it has a bearing upon the explanation of the production of the deformity. It is thought that the continued growth of the lens equatorially is due to centrifugal traction exercised by the fibres of the suspensory ligament (E. T. Collins). Hence, a limited deficiency of the fibres would entail as its necessary consequence maldevelopment of the corresponding part of the lens—or, in other words, the production of a coloboma. The explanation of the curious case reported by Mr. R. W. Doyne (*Trans. Ophthal. Society*, Vol. XI., 1891, p. 220), where coloboma of iris and choroid was associated with a projection from the corresponding part of the lens, is still to seek.

Coloboma of the Choroid.—Colobomata of the choroid may be described as (*a*) typical, and (*b*) atypical. Both forms have what may be called a fissurial origin.

(*a*) Typical cases show, when examined with the ophthalmoscope, a larger or smaller area of nacreous exposed sclera, extending downwards from the optic disc towards the visible periphery of the fundus oculi. The optic papilla may or may not be involved. The exposed sclera is often ectatic—that is to say, thrust outward, forming what is sometimes called the "scleral protrusion of Von Ammon." The exposed area generally shows here and there pigment and small vessels. Retinal vessels may cross the surface of the coloboma. Eyeballs containing colobomata are often much smaller than normal—microphthalmia. Even when the dimensions are good, colobomata usually produce a gap in the field of vision, and owing to imperfect differentiation, sight is often extremely poor. Coloboma of the choroid, according to Fuchs, "is in a marked degree transmissible by inheritance." Other defects of the eye, particularly coloboma of the iris, are commonly associated with coloboma of the choroid. With regard to the explanation of the condition, it is usually taught that coloboma arises from incomplete closure of the fœtal ocular cleft. To this view Mr. E. T. Collins has opposed the fact that in some instances the retina exists over the cleft in the choroid. This he attempts to explain by an abnormal adhesion between retina and mesoblast, whereby if this occurs before closure of the fissure, the coloboma is devoid of a retinal covering, and, if after, the retina is present, so that no scotoma exists in the field of vision.

(*b*) Apart from the condition described above, deficiencies in the choroid may occur in practically any part of the fundus oculi. We then speak of atypical coloboma. The most striking of these forms goes by the name of "coloboma of the macula," a condition in which a round or oval area of sclera is exposed in the region of the yellow spot. Its size is generally several times that of the optic disc. It is often bordered by pigment, and crossed by pigment or by vessels. The retina may or may not be present, as judged by the course of the retinal vessels and by the presence or absence of a scotoma in the field of vision. Sight is generally defective in such cases, which not infrequently develop a squint, convergent or divergent, as the case may be. The origin of macular colobomata has given rise to considerable difference of opinion, and the question even now cannot be said to have passed beyond the realms of controversy. Thus, by Nettleship and others they have been assumed to be due to severe fœtal inflammation of the parts; by Lindsay Johnson that they represented degenerated nævi; and, lastly, by v. Kölliker and others that they were connected with the fœtal ocular cleft. In order to account for the fact that while the ocular cleft was directed downwards while the coloboma was situated in the macular region, it was assumed that the eyeball underwent a rotation of 45 or 90 degrees during its development. This view has now been given up. The modern theory is that the defect originates from incomplete closure of a subsidiary ocular cleft occupying the position of the future macula. Such atypical clefts were found as long ago as 1858 by V. Ammon in the eye of the chicken and the sheep, and more recently Van Duyse (*Rev. Générale d'Ophtalmologie*, Tome XX., 1901, p. 119) has demonstrated such a cleft in a calf.

Irideremia.—It is doubtful whether the iris is ever wholly absent. In the cases to which the name "aniridemia" is sometimes applied, critical examination (supposing that to be possible) generally reveals the fact that remnants of the iris are present in the shape of fragments of tissue situated towards the periphery of the anterior chamber. In some of the cases, indeed, as in two brothers shown by me at the Ophthalmological Society (*Transactions*, Vol. XVI., 1896, p. 184), a narrow rim of iris, not exceeding 0.5mm. in width, was present. The condition affects both eyes. Defective sight and nystagmus are the rule. Heredity is a marked feature. This is well shown by a series of cases recently reported by Dr. T. K. Hamilton (*Ophthalmoscope*, October, 1905), where a father and three children (two girls and one boy) were found to suffer from irideremia.

Opaque Nerve Fibres.—There is, perhaps, no congenital anomaly of the fundus oculi that presents more characteristic ophthalmoscopic appearances than so-called "opaque" or "medullated nerve fibres of the retina." The glistening, brush-like processes of beautiful white hue, radiating from the optic disc into the neighbouring fundus, form a picture that, once seen, is not readily forgotten or mistaken for anything else. The condition finds its anatomical explanation in the fact that the medullary sheaths of the nerve fibres, which normally cease abruptly at the lamina cribrosa, are regained by some of the nerve fibres at the margin of the optic disc, and are continued into the retina as such for a longer or shorter distance. When examined with the microscope, the medullated fibres are varicose, owing to the existence of small globular or fusiform swellings along their course, but it has been suggested that these are so many artefacts. In certain animals, as the rabbit and the Tasmanian devil, opaque nerve fibres occur normally. It has been pointed out by V. Hippel (V. Graefe's *Archiv für Ophthal.*, Band XLIX, 3, p. 591) that the appearances in the rabbit do not develop until about three weeks after birth. The same writer maintains that a similar observation holds true in man. Strictly speaking, therefore, opaque nerve fibres is not a "congenital anomaly." Medullated nerve fibres is not a common abnormality. According to some figures I published last year (*Ophthalmoscope*, December, 1906), dealing with the eyes of 4,212 children, the anomaly was present in 29 cases, or 0.68 per cent. of the entire number; 72 per cent. of the cases were unilateral, and 27 per cent. bilateral. My statistics further brought out the fact that opaque nerve fibres were, roughly speaking, twice as common in the eyes of males as of females. With respect to the ophthalmoscopic appearances of my own cases, the commonest was that of one or more white, comet-like processes extending into the fundus from the upper or the lower edge of the optic disc or from both of those positions. In a much smaller number of cases the optic papilla was more or less surrounded by the glistening masses. In a single instance did the opaque fibres encroach upon the optic disc itself. In four eyes the rare condition of "eccentric" nerve fibres was noted—that is to say, areas of medullated fibres not in visible connection with the optic papilla. Cases of this description have been described by Frost, Randall, Dodd, Nettleship, Blascheck, Ulbrich, and Hawthorn. Before leaving the subject, it may just be said that opaque nerve fibres have been known to disappear in cases of optic atrophy (Sachsalber, Nettleship), or of glaucoma (Frost), presumably from degeneration of the fibres.

Pseudo-Neuritis.—The next anomaly to be described has received the name of "pseudo-neuritis," or the "hypermetropic disc." The condition is a common one both in children and in adults. In order to ascertain its frequency in the class first-named, some few years ago (*Reports of the Society for the Study of Disease in Children*, Vol. III., 1903, p. 342), I examined the eyes of 114 children, whose ages ranged from 2 to 16 years. Of the total number, I found as many as 26—that is, 22.80 per cent.—presented a greater or less degree of pseudo-neuritis. It is rather a singular coincidence that Dr. H. C. Bristowe (*Ophthalmic Review*, 1891, p. 321) found the condition to exist in 29 amongst 125 patients—that is, in 23.2 per cent—or in almost the same proportion as that given above. Some of Dr. Bristowe's best marked cases were met with in individuals over 30 years of age. The ophthalmoscopic appearances of pseudo-neuritis vary from a slight haziness to a decided woolliness of the nasal edge of the optic disc, or in extreme examples to a diffuse blurring of the papilla. The slighter grades present a deceptive resemblance to a commencing optic neuritis, while the more pronounced may be readily confounded with a well-developed optic neuritis. The change, although invariably bilateral, is not necessarily equal in degree as regards the two eyes. Two other ophthalmoscopic appearances are commonly associated with pseudo-neuritis—(1) traces of glistening connective tissue alongside the central vessels of the optic papilla; and (2) some tortuosity of the retinal arteries and veins over the fundus generally. How can we distinguish between pseudo-neuritis, on the one hand, and true neuritis, on the other? The main diagnostic points appear to me to be:—1. Pseudo-neuritis is a congenital condition, neither receding nor advancing, no matter how long a case may remain under observation. True neuritis, on the contrary, begins, attains its height, and is then replaced by atrophy or (very rarely) by recovery. Therefore, if the disc become blurred while a patient is under observation, or if blurring become more marked under those conditions, we may safely conclude that we have to deal with veritable optic neuritis. 2. Normal sight and visual field are points against the diagnosis of neuritis. 3. In pseudo-neuritis the disc, in my experience, is never appreciably swollen, although, judging from the appearance of the retinal vessels, it often appears to be so. In reference to this point I note that the latest book *on diseases of the eye*, by Mr. J. Herbert Parsons, contains the caution not to diagnose pseudo-neuritis "unless at least 2D. of swelling can be demonstrated" (p. 397). The exact etiology of pseudo-neuritis is not known, although my own investigations render it certain that it is a congenital condition. Certain writers regard it as the expression of an actual hyperæmia or congestion of the optic disc, due to eye-strain produced by hypermetropia or hypermetropic astigmatism. Hence the name "hypermetropic disc." With this view I am unable to agree, for two reasons—first, if the condition is caused by hypermetropia, it should be relatively more frequent and assuredly more pronounced in the higher than in the lower grades of hypermetropia. The figures at my disposal, however, prove that such is not the case. Secondly, it should undergo an improvement when eye-strain is relieved by suitable glasses, but I have repeatedly satisfied myself that such is not the fact. Moreover, pseudo-neuritis may occur in association, not with hypermetropia, but with myopia or myopic astigmatism. If it is more frequent in hypermetropia, it is simply because in children that condition is at least five times as common as the reverse condition, myopia. I may say that my investigations justify me in claiming that pseudo-neuritis is relatively as common in the one condition as in the other. Accordingly, I reject the name of "hypermetropic disc" unconditionally. I regard pseudo-neuritis as a congenital non-differentiation of the optic disc, a view supported by the frequent existence of shreds of connective tissue and also by the state of the retinal vessels.

Ptosis.—Ptosis may be counted among the commoner congenital defects. It may be complete, or almost so, but is usually incomplete, and both eyes, as a rule, are affected. It may be so slight as scarcely to attract attention until the child looks upwards. When ptosis is marked enough for the eyelids to cover the pupils, the patient manages to see by throwing his head backwards and at the same time evoking the action of the occipito-frontalis muscle. This gives such patients a very characteristic appearance. An interesting point about congenital ptosis is that the condition is not seldom associated with defective movements of the eyeball upward; other defects of movement are more rare. Many cases have now been recorded in which the ptosis became modified during movements of the jaw, such as occur during suckling or mastication. Similar modification has been known to take place when the eye is adducted or abducted. These cases have an interesting bearing upon the innervation of the muscles concerned, and are thought by some to confirm the theory of Mendel, according to which the levator palpebræ superioris is supplied not only by the third nerve, but also by fibres belonging to the fifth cranial nerve, which supplies the muscles of mastication. With regard to the explanation of congenital ptosis, in some cases the levator has been found to be absent, replaced by fibrous tissue, inserted abnormally, or imperfectly developed. The alternative view—namely, that the defect is due to aplasia of the nerve nuclei—is supported by a case of Wilbrand and Sänger (*Die Neurologie des Auges*, 1900), where such changes were found in a man afflicted with congenital ptosis, who died at the age of 47 years.

Persistent Hyaloid Artery.—As already explained, up to a certain period of fœtal life, the hyaloid artery runs from the optic disc through the vitreous to the lens, where it breaks up into a vascular plexus, in order to nourish the enveloping membrane of the crystalline, the so-called capsulo-pupillary membrane. Its persistence in whole or in part is responsible for several congenital anomalies of the eye. For example, in typical form it may persist as a blood-bearing vessel, originating from the optic disc, and reaching to the hinder surface of the lens or to some structure in the neighbourhood of the latter. More commonly, however, one sees merely a greyish cord, attached at one end to the disc, and at the other to the lens or else lying free in the vitreous. The vestige, again, may reveal its existence as a mere tag of tissue, attached to the optic papilla, and moving in response to the excursions of the eyeball. In connection with the hyaloid artery, it may be well to recall the fact that in some animals, as the frog, the vessels of the vitreous persist throughout life.

Anomalies of the Eyelids.—A congenital anomaly of the eyelids that seems to be connected with perverted development was described by me some years ago (*Trans. Ophthalmological Society*, Vol. XIV., 1894, p. 13), under the name of congenital trichiasis. The condition, which is not exactly rare, affects the lower lid of one or both eyes. It is characterised by the fact that more or less of the free border of the lower lid is concealed behind a horizontal fold of skin the mechanical effect of which is to push the lashes upwards, with the consequence that they come into contact with the surface of the eyeball. The cilia appear to be normal, except as regards their direction. The intermarginal space is almost, if not quite, normally situated. The condition may be combined with epicanthus. Heredity is marked. The condition, I believe, depends essentially upon a relative maldevelopment of the tarsus of the lower lid. A more pronounced maldevelopment of that structure, as suggested by Guibert (*Archives d'Ophtalmologie*, February, 1892), would produce the exceedingly rare condition of congenital entropion. A few cases have been known (Jago, Streatfeild) where patients could invert the lower lid at will.

Another interesting but very uncommon malformation affecting the cilia goes by the name of distichiasis, of which I reported a typical case to the Ophthalmological Society in 1901 (*Trans. Ophthalmological Society*, Vol. XXII., 1902, p. 192). This malformation is marked by the existence as a congenital condition of a second row of lashes lying behind the normally placed ones. Upper as well as lower lid may be involved. Mr. A. R. Brailey (*Trans. Ophthalmological Society*, Vol. XXVI., 1906, p. 16) examined microscopically a small piece taken from the upper eyelid of a patient with distichiasis. He found that the most striking feature was absence of the Meibomian glands. Kuhnt regards distichiasis as a congenital condition in which the Meibomian glands have been replaced by a row of accessory cilia with all their attributes as sebaceous glands. The influence of heredity was well shown by Erdmann's cases (*Zeitschr. für Augen-*

heilkunde, May, 1904), which occurred in three generations of the same family, affecting grandmother, mother and child.

Anomalies of the Lacrymal Apparatus.—In a singular case reported by A. S. Morton (*Trans. Ophthalmological Society*, Vol. IV., 1884, p. 350), there was a congenital absence of lacrymation as regards one eye, and in another case by G. Sommer (*Klin. Monatsbl. f. Augenheilk.*, 1903, Band I., p. 482) as regards both eyes. It does not quite follow that the lacrymal gland was absent, although that was actually proved to be the case in an instance of cryptophthalmia examined by Van Duyse. Fistula of the lacrymal gland has been reported by several authors, as Mackenzie and McGillivray. As relatively common conditions the puncta lacrymalia may be absent, replaced by a shallow groove, or blocked up—all as developmental anomalies. The puncta, moreover, may be multiple. By far the commonest and most important anomaly, however, is due to the imperfect differentiation of the naso-lacrymal duct, together with subsequent infection, a condition to which the name "congenital dacryocystitis" is sometimes applied. Should canalisation of the duct be incomplete at birth, it needs only infection by pyococci or other organisms, as the pneumococcus, to cause a discharge of muco-pus from the puncta. The infection, indeed, may occur in the maternal passages, in which event the baby is actually born with a discharging lacrymal sac. In other cases, which perhaps form the majority, the infection is *post-partum*, so that the characteristic appearances do not manifest themselves for several days after birth.

Dermoids.—Dermoid cysts or growths are found with tolerable frequency, either alone or associated with other anomalies, upon or about the eye. All of them are to be explained by epiblastic sequestration taking place while the embryonic clefts are in process of closure. They thus form one of the best examples of the well-known embryonic hypothesis of Cohnheim. Few of the dermoids about the eye deserve the more dignified title of teratomata—*i.e.*, growths which include highly organised structures such as bone or teeth. The commonest place for a dermoid to occur is at the outer end of the eyebrow, where it forms a lenticular swelling, not attached to the skin. These small growths seldom penetrate deep into the orbit. It is therefore more correct to speak of them as "peri-orbital" than as "orbital." Their wall contains some or all of the elements found in skin, while their contents consist of sebum, or—much more rarely—of oily liquid—the so-called "oil cysts." Although the cysts are, of course, congenital, yet they may grow considerably subsequent to birth. I have known them appear more or less suddenly after injury to or operation on the parts. The peri-orbital dermoid may occur at the inner side of the eye, near the root of the nose, a position in which it must be carefully distinguished from a meningo-encephalocele, now believed by many to result from intra-uterine hydrocephalus. On the other hand, true orbital dermoids are extremely rare. I have seen one case only of the kind. The dermoid of the eyeball usually takes the form of a small, solid, whitish growth, of firm consistence, astride some part of the limbus conjunctivæ, as a rule, on the lower and outer aspect. Fine hairs may protrude from the surface of the dermoid, and towards puberty these may grow to inordinate length. In Wardrop's famous case (*Essays on the Morbid Anatomy of the Human Eye*, 1808, p. 31), upwards of a dozen long and very strong hairs grew from the middle part of such a tumour, passed between the eyelids, and hung over the cheek. The patient remarked that these hairs did not appear until he advanced to his sixteenth year, at which time also his beard grew. Dr. Argyll Robertson, under the name "trichosis bulbi," has described (*Trans. Ophthalmological Society*, Vol. XIV., 1894, p. 196) a similar but slighter growth of hair from a dermoid thickening of the ocular conjunctiva. The last form of dermoid to be mentioned appears beneath the ocular conjunctiva, usually in the interval between the insertion of the superior and external rectus tendons, as a soft, fatty-looking mass, the conjunctiva over which may show no particular changes to the naked eye. These growths, formerly spoken of as "congenital fibro-fatty tumours," are now generally recognised to be lipo-dermoids. They are not encapsulated, and their contained fat is continuous with that belonging to the orbit. Their complete removal is therefore an impossibility.

II.—ANOMALIES DUE TO AMNIOTIC ADHESIONS.

As explained earlier, certain anomalies of the eye are now believed by many to be due to the bad effects upon development exercised by adhesions between the amnion, on the one hand, and the tegument of the fœtus, on the other. As to the exact conditions under which such adhesions occur, we have still much to learn. It is, however, admitted that scantiness of the amniotic fluid—that is to say, the condition known as oligo-hydramnios—is a predisposing factor. Gonorrhœal infection *in utero* is probably also a factor in some cases of amniotic adhesions (J. B. Hellier).

The outstanding anomaly for which amniotic adhesions seems best to account is coloboma of the eyelids. Dor and Nicolin (*Revue Générale d'Ophtalmologie*, December 31st, 1888) trace coloboma to an interference with the development of the eyelids by imperfect closure of the oblique facial fissure. On the other hand, in recent times more particularly, Van Duyse thinks the malformation to be closely connected with the presence of amniotic bands. Van Duyse's theory, as pointed out by J. H. Parsons (*The Pathology of the Eye*, Vol. III., Part I., p. 778), explains not only the coloboma, but also the cutaneous ridges and dermoids as persistent portions of the constricting bands. Dor's objection, that amniotic adhesions cannot account for the existence of bilateral and symmetrical colobomata (*loco citato*, p. 532), is met by the observations of V. Bruns, Pollailon, and Lannelongue, who observed such bands inserted into the middle of the cornea and passing symmetrically over the eyelids.

Coloboma of the eyelids is far from common, as may be inferred from the fact that Nicolin, writing in the year 1888 (*Thèse de Lyon*, 1888), was able to bring together 46 cases only from the collective literature.

Coloboma may range as regards degree from a tiny notch in the free border of the eyelid to a wide gap extending through the entire structure and exposing the cornea. The cilia are nearly always absent from the hiatus. In about 50 per cent. of the cases one eyelid is alone affected, and the upper is the seat of election. For example, among 90 cases of coloboma collected from literature for the purposes of this lecture, in 46 one eyelid was alone involved—that is, the upper in 36 and the lower in 10 instances. The collection included only two cases—namely, those by Lannelongue and by Morian respectively—where all four lids were implicated. Morian's case is suggestive, since the colobomata were associated with amniotic strangulations of the patient's fingers and toes, in addition to oblique facial clefts healed *in utero*. In some of the cases the coloboma was connected by a cutaneous fold with the eyeball, and in many others a dermoid growth existed in such a position on the eyeball as to fill more or less completely the gap left by the coloboma when the lids were closed. At the same time it cannot be denied that these defects in the lid, especially when large, predispose to ulceration of the cornea, as in cases reported by Conradi (1888), Cowell (1891), Juler (1892), and myself (1906). Hence, besides the deformity often caused by the coloboma, we have another and a very good reason for closing the gap in the lid as early as may be. In this connection it may be stated that 16 of the 90 patients included in my series had been treated surgically.

It is worth mentioning that in only six of the ninety cases of coloboma of the lid no associated deformities of the eye or of other parts of the body were alluded to in the authors' descriptions (Talko, Gillette, Despagnet, Major, Galezowski, and Creutz). Details, however, were often scanty. Curious tufts of hair arising from the eyebrow and directed towards the coloboma have been reported by Nuel, Frost, Morian, and Ohse. In Manz's case (V. Graefe's *Arch. f. Ophthalmologie*) of coloboma of the median part of each upper lid, the middle third of each eyebrow was absent. Notched orbits or deficiencies of the eyebrow have been reported by Nuel, Hassalmann, Schanz, and

Geissmar. Cicatrices, representing Nature's attempt at cure, have been noted by Snell (*Trans. Ophthalmological Society*, Vol. 1884, p. 348), Berry, and Rosa Ford (*Ophthalmoscope*, 1907), extending in the skin from the cleft towards the orbital margin. A similar line has been seen by E. T. Collins (*Trans. Ophthalmological Society*, Vol. XXV., 1905, p. 319) in the palpebral conjunctiva. The ocular complications of coloboma, in addition to those mentioned before, include epitarsus, pupillary membrane, coloboma of iris and choroid, adherent leucoma, notched optic disc, multiple or absent lacrymal puncta, and ectasia of the lacrymal sac. The general deformities most commonly noted in these cases have been deformed or supernumerary auricles, ill-developed malar prominences, macrostomia, post-anal dimple (so-called fovea sacralis), highly-arched palate, bifid tongue or uvula, stenosis of the nostril, absence of the external auditory meatus, hare-lip, cleft palate, and, lastly, oblique facial fissure or its remains.

It may be added, before passing from the subject, that cases have been described by Berry, E. T. Collins, Tyrrell, and Rosa Ford, where a small notch in the outer part of the lower lid, generally of both eyes, coincided with mal-development of the malar bone, as shown by flattening of the side of the face. The group, although not large, is important, inasmuch as the cases can be readily explained by the theory of amniotic adhesions.

(To be continued.)

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Sydney Stephenson, M.B.Edin., F.R.C.S., Ophthalmic Surgeon Evelina and North-Eastern Hospitals for Children, Kensington General Hospital, &c. Subject : "Congenital Anomalies of the Eye" (Part II.)*

ORIGINAL PAPERS.

THE DISEASES AND DISPLACEMENT OF THE TESTICLE IN CHILDHOOD. (a)

By D'ARCY POWER, F.R.C.S.Eng.,

Surgeon to and Lecturer on Surgery at St. Bartholomew's Hospital.

THE diseases of the testicle in children group themselves naturally under the headings of tubercle, syphilis, malignant growths, innocent tumours, and teratomata. The displacements are due to faulty processes of development carrying with them certain additional predispositions to disease and injury.

In opening a discussion on the subject the results of personal experience are given and questions are asked in regard to points which appear to stand in need of further elucidation.

TUBERCLE.

Most of the swollen testicles seen in the wards and out-patient rooms of a children's hospital are caused by tubercle or by syphilis, or, perhaps, speaking more correctly, by tubercle growing in tissues which have been prepared for infection by changes due to congenital syphilis. In private practice they are nearly always tuberculous without any admixture of syphilis.

Tuberculous disease of the testicle is rare in children, for Demme records 16 cases in 1932 tuberculous children, whilst Jullien only saw it 16 times in 5,516 children. But tuberculous inflammation of the testicle in children is much more common than these statistics show, and there is never a year in which two or three children do not come under my care for this form of disease. The inflammation is sometimes primary, but it is more often associated with other signs of tubercle, and there is frequently a definite history of injury. It is usual, therefore, for only one testicle to be affected. The diagnosis is easy, but the disease runs a somewhat different course in children from that which it follows in adults, because the gland is not functional in children.

When the infection is simple and the child is fairly healthy, the disease may remain localised to the affected gland. The swollen testicle is enlarged for a longer or shorter period, and then slowly diminishes. The inflammation disappears completely and the testicle may resume its original condition, or the process of involution may be carried beyond the normal, the testicle atrophies, and the child becomes monorchous. This, at least, is the statement generally made, but I should like to know if anyone has followed out the progress of a tuberculous testicle until it ended in atrophy. I have seen atrophy four years after an operation for the radical cure of a hernia in a child, and I have seen it after enlargement of the testicle due to congenital syphilis, but never as a result of tubercle.

The treatment of these cases of pure tuberculous infection may safely be palliative. Fresh air, cream, or cod liver oil, good food, and plenty of sleep, with a light suspensory bandage, are sufficient. But a jealous eye should be kept upon the child, and he should be weighed at frequent intervals. If the weight falls a careful and systematic examination should be made to ascertain whether there is any evidence of dissemination; the lymphatic glands, the bones, more especially the vertebræ, the peritoneum, the pleuræ, and the meninges of the brain are the most likely parts to become affected. The testicle should be removed at once when there is even a suspicion of such an infection.

The prognosis is not so good when the infection consists of a mixed culture of tubercle bacilli and pyogenic organisms. In such cases an abscess is soon formed, and the neighbouring lymphatic glands quickly become affected.

I would, therefore, counsel early removal of the testicle when suppuration occurs, because I do not believe that any good follows such partial operations as the scraping or excision of the softened parts of the testicle, but rather harm, for I have often seen these cases associated with tuberculous dactylitis, spinal caries, and tuberculous peritonitis.

SYPHILITIC INFLAMMATION.

Syphilitic inflammation of the testicle occurs at all ages from birth up to four and twenty, though it is most common before the age of three years. Both testicles are affected, and often at the same time. A hydrocele of the tunica vaginalis is an almost constant accompaniment, whereas in a tuberculous testicle a hydrocele does not occur in more than a third of the cases. The patient, if he be an infant, always presents evidence of inherited syphilis, often in a severe form. The testicles are extremely hard, and the beneficial effects of administering gray powder are so marked as to leave no doubt about the diagnosis.

The inflammation is usually diffuse, and leads to a general enlargement of the body of the testicle, but it is occasionally gummatous, in which case the outline is irregular. The epididymis may be affected, but it is much more usual for the tunica vaginalis to be involved in the inflammation, a feature which accounts for the frequent co-existence of a hydrocele. It is rare for suppuration to take place in syphilitic inflammation of the testicle so long as it is free from tuberculous infection; but it is quite common for the two infections to co-exist in the miserably marasmic children who are the subjects of these swollen testicles. The condition is so painless and chronic that it is often overlooked, and children are occasionally brought for advice in whom the process has continued for so long that cicatricial contraction of the inflammatory fibrous tissue has occurred and the testicle is atrophied.

I should like to know in connection with syphilitic inflammation whether any observations have been made as to the retardation of puberty which takes place as a result of inherited syphilis. I believe it to be part of a general failure of development and that it is not a mere consequence of the atrophy of the testicles, or of the ovaries, for the delay occurs in both sexes. It is certain that the patient is impotent as well as sterile when both testicles are wasted owing to inflammation due to inherited syphilis.

(a) **Abstract of Paper read in the Section for Diseases of Children of the British Medical Association Meeting at Exeter, August 1907.**

Teratomata.

Teratomata of the testicle are always cystic, for they are either dermoids or sebaceous tumours. Dr. Hilton, of Nebraska, collected the records of 79 cases. In these the teratoma was testicular in origin in 40 patients and scrotal in 21; in 14 cases it was situated in the inguinal canal and in one case it was derived from the tunica vaginalis.

These tumours form an interesting group and open up many points for discussion, as well as for elucidation by more careful examination. It is not yet known, for instance, whether a dermoid of the testicle is, or is not, a true tumour of the testicle itself. Indeed, the ease with which it can sometimes be dissected away from the gland makes it highly probable that in many instances a dermoid is in reality a teratoma, using the term in the sense of a parasitic fœtus. It is highly desirable, therefore, to determine, as far as possible, in each case whether the dermoid is within the tunica albuginea; whether it merely lies in the connective tissue between the tunica vaginalis and the testicle, or whether it is clearly attached to the scrotum, and, if so, whether the attachment is due to its being the place of origin of the tumour or the result of inflammatory changes between the scrotum and the wall of the dermoid. A section through the wall of the dermoid may show the presence of atrophied seminiferous tubules if the tumour has been developed within the substance of the testicle.

Dermoids are so rare that an error of diagnosis is pardonable, and it seems that they are most likely to be mistaken for epiploceles and for hydroceles of the cord. They are distinguishable from hydroceles by the absence of that translucency which is invariable in infants, and from omental hernia by the fact that teratomata are more uniform in outline, whilst the careful examination of an epiplocele will often reveal the presence of nodules. Complete reduction is no more possible in the case of a teratoma than in that of an encysted hydrocele, but in both cases it may be possible to push the tumour out of sight through the external abdominal ring.

There is no question as to treatment. The swelling in the scrotum should be explored, and the dermoid removed without sacrificing the testicle, if possible, but if it be actually incorporated with the gland the whole organ must be removed, as there is a definite liability to inflammation, suppuration, or hæmorrhage after slight injuries. It would be interesting to learn if any one has yet seen teratomata affecting both testicles—for teratomata of both ovaries are not very rare.

Malignant Disease.

Sarcoma of the testicle occurs in boys æt. 10 and upwards, and, like sarcomata elsewhere they follow directly upon an injury in a considerable proportion of cases. The tumour primarily involves the epididymis, and the body of the testicle is less frequently involved at first. But the growth often runs a very rapid course, and much time is usually lost because it is painless and there is early loss of testicular sensation. The patient therefore does not apply for relief until the tumour has attained a sufficient size to make it inconvenient by its weight. The tumour is then found to be smooth, heavy, and hard, but its shape and even its very existence may be masked by the presence of a hydrocele or a hæmatocele. The affection is most likely to be mistaken for a thick-walled hydrocele, for tubercle, or for syphilis, but the rapid growth of a sarcomatous testicle soon indicates its real character.

I believe the prognosis of sarcoma of the testicle to be worse in boys and young men than it is in old people, for all the cases I have seen have ended fatally, even when an early operation has been performed. A misleading feature about the patients is that they remain in singularly good health for a long time, and it is difficult, therefore, to persuade either them or their friends that they are suffering from a deadly disease. Too much stress in these cases must not be laid upon the existence of enlarged lumbar glands, because, although they are often affected, I have seen more than one case in which there was diffuse sarcomatous infiltration of the whole peritoneum spreading from the epididymis up the spermatic cord without any infiltration of the lymphatic glands.

Mr. Eve (*Trans. Path. Soc.*, Vol. 38, p. 201) and Mr. A. G. R. Foulerton (the *Archives of the Middlesex Hospital*, Vol. 5, p. 234, and the *Lancet*, 1905, Vol. II., p. 1827) have shown the need for reconsidering the whole question of those tumours of the testicle which are usually called sarcomatous. Many of the tumours are really columnar-celled carcinomata beginning in the tubules of the rete testis or in the vasa efferentia. It would be interesting, therefore, to know whether, in the light of Mr. Foulerton's work there is any difference in the course and dissemination run by malignant tumours of the testicle when the deep lumbar glands remain unaffected and when they become early affected. I think it will be found that there are two classes, and that the patients in whom the lumbar glands are unaffected die sooner than those in whom they are early enlarged.

Imperfectly descended Testicle.

The questions connected with imperfect descent of the testicle open up such wide fields for discussion that it would easily form material for an entire debate. I shall, therefore, endeavour to narrow it down to a few practical points. Brushing aside all theory, I should like to ask, what is the general feeling about orchidopexy or the freeing of a testicle, which is imperfectly descended, with subsequent fixation to the bottom of the scrotum, the pillars of the external abdominal ring being afterwards sutured to prevent the testicle from re-entering the inguinal canal? I have done the operation many times, but, except in the very simplest cases, I have never satisfied myself that it was advantageous, and in a few cases the result has appeared to be so unsatisfactory that I have afterwards removed the testicle.

I think, therefore, that it is better to advise removal of the testicle in nearly all cases where it is imperfectly descended and can be felt, especially if there is evidence of a hernia and the abnormality is limited to one side.

When a hernia is present the sooner the operation is done the better after the patient has attained the age of four or five years. When there is no hernia, or only a small bubonocele, I generally advise the parents to wait until the child is seven or eight years old in the hope that the testicle may descend further into the scrotum. But I do not think it is worth while waiting until puberty, because a fairly accurate prognosis can be arrived at much earlier if the child is seen a few times at intervals of two or three months.

I have lately had two cases of acute torsion of the spermatic cord under my care, and in both cases the testicle was imperfectly descended. I contented myself in the first case with untwisting the cord, and was rewarded for my forbearance, but in the other case the testicle was removed, and the ring sewn up.

But the really difficult cases of imperfectly descended testicle are those in which the only son of influential persons is brought for advice at the age of five with both testicles lying within the inguinal canal close to the external abdominal ring. I see my way clearly when only one testicle is imperfectly descended, when the imperfect descent is associated with a hernia, as is the case in about 80 per cent., and when pain or symptoms of torsion have appeared. I know also what to advise when both testicles are situated comfortably in the abdominal cavity; but I confess that I am doubtful as to the best course to pursue when both testicles are situated within the inguinal canal at a point where they may be readily injured in the ordinary course of school life. They ought not to be removed, especially if large interests are at stake, and I therefore suggest that the wisest advice is either to leave them alone until they become troublesome, or else to put them straight back into the abdominal cavity. But if the latter course be adopted, the operation should be done early, as there is evidence to show that testicles thus replaced after puberty do not undergo development, whilst if they be replaced earlier the testicle may produce spermatozoa a few years between eighteen and twenty-five. It is then possible that the testicles may become functional, at any rate for a short time, though too much must not be promised to the parents. All that one can say is, that the boy will not then present the characters of a eunuch, and that he has been put into the best possible condition, under the circumstances, for the subsequent procreation of children.

An ectopic testicle must be treated on its merits. When it lies in the perineum, the gland may easily be put into the scrotum, for it is often attached to the tuber ischii, to the external sphincter of the anus, or to the skin by a single band of fibres which can be made tense. The subcutaneous division of this band sometimes allows of the testicle being replaced in its proper position, or, if this fails, an open operation may be performed, and the testicle can then be put into the scrotum. But when the testicle lies in the groin or in the femoral region, I do not hesitate to remove it, first, because testicles so placed are said to be always functionless, and, secondly, because they are more especially liable to injury.

HYDROCELE.

Of all the tumours in the scrotum of children, I think that an ordinary hydrocele is the most often overlooked or misinterpreted. Everyone is alive to the fact that children suffer from hernia, but students and practitioners alike seem to forget that hydrocele is nearly as common in infants as it is in adults. Children are, therefore, constantly brought to the surgeon with a diagnosis of rupture when a little care in examination would have shown that the swelling was in reality a hydrocele. The mistake is not very excusable in a case of hydrocele of the tunica vaginalis, though it is venial if the swelling be limited to the cord, especially if it be situated at or near the inguinal canal. The error in diagnosis is unimportant if a woollen truss be ordered, but serious harm may be done if determined attempts are made to replace the swelling within the abdomen, or if it be treated as a strangulated hernia, because from other causes the child has become constipated. In my own case I base the diagnosis very largely upon the sense of touch. A hydrocele always appears to me to be much more tense and elastic than any hernia I have ever felt. I am careful to place no reliance upon the translucency of the tumour, because I know that in young children the walls of the bowel are so thin as to transmit light quite easily. I know, too, that in babies a hydrocele is not so often pear-shaped as it is in adults. It may be so tense and well defined round the testicles that it moves quite easily in the scrotum, and it is often taken, therefore, for an enlarged testicle. Treatment, I think, should consist in simple puncture, but if the hydrocele refills there need be no hesitation in performing a radical operation even in very small babies, the operation being carried out on the same lines as in adults.

MEDICAL SUPERVISION OF SECONDARY SCHOOLS IN SWEDEN. (a)

By Dr. MED. GOTTFRID TÖRNELL.

To a certain extent Sweden may claim to be regarded as a pioneer country in respect of the appointment of medical officers in conjunction with the State schools. Mention is made of such officers as long ago as between 1830 and 1840, and in 1863 there was issued an ordinance prescribing the duties they were required to fulfil. It is fair to assume that as early as 1868 all the public schools in the kingdom had medical officers attached to their staffs. The school Codes of 1878 and 1892 contained paragraphs which still further extended the sphere of activity in the school allotted to the medical officer. The Code at present in force bears date February 18th, 1905. It contains detailed prescriptions concerning the duties of school medical officers, drawn up entirely in accordance with modern hygienic principles.

The work which is considered in this country (Sweden) to come within the purview of a school medical officer may be summarised under the following headings:—

1. To examine the scholars medically, in order to find out the state of health of each.
2. To adopt preventive measures against the spread of infectious complaints.
3. To superintend the school premises as regards their sanitary condition.
4. To provide against the scholars being overburdened with lessons, etc., and thereby becoming overworked.
5. To attend indigent children in case of illness, free of charge; and
6. To draw up statements upon any problem that may arise regarding school hygiene, and to hand in periodical reports of the work that it has fallen to their lot to discharge.

It is in accordance with the principles above stated that the "Instructions to School Medical Officers," issued as one section of the new Code of 1905, have been formulated.

The State Secondary Schools Supervisory Board has at its disposal the services of an expert in hygiene, and he is consulted on matters belonging to that aspect of education.

On the staff of every school there shall be a medical officer—appointed and remunerated by the State—whose duties are:—

1. To examine candidates for entrance to the school free of charge, if they are in indigent circumstances.

[In order to obtain entrance into a State secondary school, a candidate must be furnished with certificates to show: That he or she has been vaccinated, and that he or she is not a sufferer from any illness or defect which would render him or her unfitted to take part in school work, or which might exercise a deleterious influence on his or her schoolfellows.]

2. At the beginning of every term, in the presence of the teacher of gymnastics, to carry out a careful investigation of each one of the pupils, and to hand in to the headmaster or the class superintendent a report upon the result of such investigation. The pupils' sight and hearing are to be tested once every year.

3. To conduct a medical examination of any pupil, either at the suggestion of the headmaster or otherwise, whenever his or her state of health seems to require it.

4. To afford the headmaster any advice that may be necessary or expedient in case of an outbreak in the school of any infectious complaint, and to take measures to prevent the spread of the infection. A definite period of absence from school in the case of pupils having caught some infectious complaint, varying with the nature of the disease, is not prescribed by the school Code. In no case, however, is it permissible for a pupil who has had any such illness to return to school until the school medical officer shall have pronounced him or her free from infection, and have drawn up a certificate to that effect.

5. To attend indigent children free of charge. This article does not now appear in the school Code; it has long been in force with reference to Swedish public schools.

6. To inspect all the school buildings thoroughly, and to be present at the teaching of gymnastics at least once a month. In regard to the latter duty, attention should be particularly directed to seeing that the pupils are not set to execute movements or do exercises which are unsuited to their physical powers.

7. To spend at least one hour per week on the school premises, for the purpose of affording advice, if such be needed, to the headmaster, the other masters, or the pupils. This hour of attendance is to be employed partly for the reception of any member of the school community who desires to consult a medical man, and partly for the inspection of the conditions under which

---

(a) Read before the International Congress on School Hygiene, London, July, 1907.

the pupils do their work; how they are seated as regards light and air, etc., how they sit at their desks, the posture of their bodies, etc., and what degree of mental alertness they display at their lessons, etc., etc.

8. To supervise the curriculum of work. The chief point for the medical officer to observe here is whether work and leisure are suitably apportioned in the curriculum, so as to avoid the occurrence of overstrain among the pupils. If the medical officer finds cause to disapprove of the curriculum in any particular, he should bring the fact to the notice of the headmaster.

9. To hand in annual reports upon duties performed by virtue of office.

10. When new buildings are being erected or old ones altered or repaired, to make sure, provided no other specialist in hygienic matters is called in, that the requirements of hygiene are being duly and adequately fulfilled in the building work as it proceeds.

11. To be present at any meetings of the staff of the school where questions pertaining to the health of the pupils or the sanitary arrangements on the school premises are being debated; to take active part on such occasions not only in the discussion, but likewise in the voting or drawing up of the resolution of the meeting.

[Thus, as far as hygienic matters are concerned, the school medical officer is not merely an advisory member of the staff; he is also empowered to assist in the framing of decisions.]

The school medical officer has furthermore to do what in him lies to see that the regulations laid down respecting physical education and the sanitary arrangements at the school are duly observed and carried out.

These regulations are, briefly, as follows:—

(*a*) The schoolhouse should be in a healthy situation, with plenty of space near it for outdoor games; a so-termed play-shed for resting, sheltering or hanging clothes in should be erected on the outskirts of the playground.

(*b*) The rooms intended for teaching in, etc., are to be constructed in accordance with regulations issued specially in regard to them.

(*c*) The gymnasium must be provided with a changing-room, a douche and a bath-room conveniently near at hand.

(*d*) Opportunities should be provided during the summer for the pupils to receive instruction in swimming.

(*e*) With reference to the heating, ventilating, lighting and cleaning of the various rooms, lobbies, etc., in the school buildings, the headmaster shall draw up, in consultation with the school medical officer, a detailed plan of procedure, to be scrupulously followed out by those whom it concerns. A copy of that plan of procedure should be nailed up on the wall in some suitable place in the school building.

(*f*) To each pupil there should be allotted about 6 cubic metres of space and 1¼ square metres of floor area. The pupils' desks should vary in size to accommodate scholars of different heights. Short-sighted and deaf pupils are to have suitable places assigned to them by the school medical officer.

(*g*) Text-books, etc., are to be printed in a type which is sufficiently large and clear to preclude any danger of the sight of the pupils being injured by the use of them.

The school medical officer is not required under the present Code to do any teaching work.

Any qualified doctor may apply for and obtain the appointment of school medical officer. It has not been considered essential that he should have gone through a special course in school hygiene, inasmuch as instruction in hygiene forms part of the course of study which all medical students take up when preparing for their qualifying degree.

What the effect of the new Code will be as regards the health of the school children it is as yet difficult to determine, for only a brief period of time has elapsed since it became law. If it is fair to judge, however, from the results already observed, and, above all, from the exceedingly cordial co-operation that prevails between the teachers and the medical officers at the schools, there is every reason to believe that the new Code will work very beneficially in the interests of the generation now attending school.

THE BEGINNINGS OF DISEASE—THE PASSAGE FROM HEALTH TO DISEASE.

By J. LIONEL TAYLER, M.R.C.S., L.R.C.P., Lond.

It seems probable—though no figures worth quoting are available, as there is no general registration of disease—that quite 30 per cent. of the general practitioner's patients could be classed under the above heading as being midway between the state of health and that of disease; and, as far the greater proportion of all illnesses are seen by the ordinary medical man, this means that from 20 to 25 per cent. of all practice is concerned with such phenomena.

I am purposely excluding from this article the beginnings of specific diseases, for these can be more appropriately considered by themselves in reference to certain more or less obvious, possible channels of infection by which specific germs can gain access to the organism. The question of simple impairment of health can thus be studied by itself, and as this constitutional failure accounts for the presence of at least three or four patients out of every ten in the ordinary doctor's waiting-rooms and for nearly a like proportion of cases on his visiting lists, it is surely profitable to give the matter some attention.

There are many popular designations for this condition of which "run down," "out of form," "seedy," "below par," "off colour," are examples, and such a phrase on a patient's lips calls up to the medical man's mind a definite, or rather very indefinite, group of related symptoms. For this state the general practitioner uses one word—debility—more frequently than any other, and he recognises a chronic as well as a temporary form, and often refers, when granting medical certificates, in writing to them. It would, however, be more accurate if patients suffering in this way were divided into three instead of two groups. The first, to be restricted to those individuals whose breakdown is slight, and the subsequent convalescence, complete and relatively permanent; the second, to those who recover much of their original health but tend to breakdown again at frequent intervals, the recurrent cases; and the third, those who seem to have acquired a chronic ailing habit and are never, or very seldom, free from a weary tired feeling and general malaise.

It has, however, to be borne in mind that an even earlier condition exists which medical men are very seldom indeed consulted about, namely, those slight failures in health that last for a few hours, and only come to our notice when they repeat themselves sufficiently frequently so as to be an annoyance to the patient. Chemists, however, often have customers drop in for a dose of "tonic" or a "pick-me-up," and though in many cases such people are only feeling the reaction of unhealthy excesses of the day before, yet there are others in whom this feeling marks the first onset of a failing constitution. Hence we may speak of these "low," "done up," "limp" feelings as symptoms of the earliest form of divergence from health, and therefore these occasional or recurrent indispositions are intermediary stages, shading more and more deeply by insensible gradations from health towards debility and disease.

The importance of these phenomena has never been sufficiently appreciated. Their prevalence is so common and widespread over the whole population that no single individual, however healthy, entirely escapes, and the inconvenience that is caused is manifest, so that the need for good treatment is great, while their scientific value is not less obvious, as the practitioner is presented with the most generalised pathological data that exist. Disease is thus seen in its embryonic state, and its development from this point to definite recognizable disorders should be clearly traceable.

The symptoms are legion, and the diagnosis is always arrived at by a process of exclusion, for on examination organic disease is found to be absent. The central factor, however, that meets one, from whatever point of view the symptoms are studied, is that of lassitude, weakness and flaccidity. The flabby, pendulant character of the voluntary muscles, when placed in a relaxed position, is obvious to the eye and touch. The collapsible condition of the smaller arteries is shown by the passive modifications in circulation that posture makes—defective peristalsis by constipation, flatulence, and occasional diarrhœa. In a woman, often menstrual irregularities disclose a weakened uterine wall. The skin is deficient in elasticity, is readily marked by any external body, and the impression thus made disappears slowly. Everywhere there is evidence of lack of tone. There may be nervous irritability or apathy, excitability or depression, but the one common complaint of patients is, "I can't settle to anything." Boils or small spots are quite common, and a loud throat cough, with thick relaxed voice and slightly reddened congested throat, are often noticeable. In nearly all people there is some increase of pallor, due possibly to a defective blood condition, and in some a muddy, putty-like complexion, with a damp, cold skin, are typical associations. In extreme cases the whole appearance is strikingly feeble, drooping shoulders and stooping figure, and a resigned, effortless, beaten expression of face.

The causes of this disordered functioning are multiform—overwork, unsuitable vocation, bad housing, monotony of life, dissipation, self-indulgence, sexual excess and abuse, laziness—anything, in fact, that impairs by excess of use or from too little exercise the tone of the body and mind.

Advice differs according to the cause. For the overworked, rest; for the underworked, activity; for the dissipated, restraint, but tonic treatment and change are rightly prescribed to all. In the vast majority of instances the patient benefits surprisingly, and a few weeks are sufficient to produce a nearly complete recovery. But there are, as we have seen, recurrent and chronic cases, and in these the disability once established tends to pass into a permanent neurasthenic condition, and it is then, when it is really too late, that the specialist is often called in, and he may fail to realise that the patient has been getting weaker and weaker for many years, treated first by some local chemist, later perhaps by some quack, later still by a local practitioner, till at the last, as a forlorn hope, a mental expert is consulted. Many of the poorer struggle on, especially those who are overworked, without treatment, because their living depends on their daily attendance at their employment. And, because no disease can be specified so that leave for convalescence might be granted, they drag out a weary existence till a final breakdown occurs. Sometimes this termination ends in insanity; sometimes a shiftless feeble character is produced; sometimes an acute illness, such as rheumatic fever or influenza, may still further cripple or afford the necessary opportunity for rest and recuperation; but from any point of view, I am convinced that more care is needed than is ordinarily given to such patients.

There are many interesting questions that this study of indisposition and debility raises. I think it will be generally admitted that the presence of excess of toxic material in the blood and tissues is one of the principal factors in the situation. This is shown by the similarity of this debilitated state to the prodromal stages of ascertained infectious and contagious diseases, and also by the happy results that follow suitable exercise, rest, simple dietary, and mild elimination treatment. But the aspect that should be of greatest importance to the scientific and practical medical man is the relation of the particular constitutional bias of the individual patient to the individual peculiarities of the symptoms that appear. For while weakness is complained of by all, no two cases are identical.

One mentions headache; another neuralgia; another sleeplessness; another sharp twinges and stiffness in the muscles and the joints; yet others allude to backache; difficulty in breathing and a sense of suffocation; persistent nausea at the sight of food, and so on. In not a single instance, if care be taken in obtaining particulars, will it be found that general debility, always the principal symptom, is the only one; for local disturbances varying with the patient are also present, and the same local phenomena tend to reappear in the same person. To the scientific practitioner, therefore, these minor differences afford clues, *if the same individual symptoms are evident in more than one attack*, of a probable natural constitutional predisposition to disease in the direction of the distinctive symptoms. And were careful records kept, I believe it would be found, in the majority of instances, that later specific diseases tend to follow the line of susceptibility thus revealed. If this be so, methodically compiled medical notes of patients would enable us to trace more accurately the beginnings of disease and treat it more scientifically, in addition to being able to warn patients how to avoid what is thus early threatened.

But apart from this, the individual treatment of debility leads at once to more favourable results. For while the major symptom is always in some degree benefited by tonics, yet the minor ones, differing in each case, are often sufficiently important to check recovery. Sleeplessness, for instance, is often due to flatulent distention of the bowel, and when the tonic, alone or even continued with a hypnotic, fails, the simple addition of a harmless carminative, like ginger or peppermint, perhaps combined with carbonate of soda, will often give very favourable results. In like manner pain in the back, which is neither of ovarian nor of dyspeptic origin, will disappear by the use of citrates, and with it a depression that had before persisted, showing, though no albumen be present in the urine, that the kidneys had been unable to eliminate toxic substances from the blood. Similarly, a feeling of suffocation will give way at once to better ventilation or to a change to the seaside.

One other consideration is worth dwelling upon. Is the debilitated individual exposed to greater immediate risks by the mere fact of his or her debilitated state? It is not easy to answer this question positively, but it seems likely that, as in tubercular diseases, debility is now an accepted predisposing cause. It is extremely likely to be so in others, but how far it is a small or large factor has yet to be determined.

A good deal might be written on the variable physiognomy that patients present: the careworn appearance of the overworked, the soft, round fatness of form of many who owe their trouble to wealth and inactivity, and the lined, baggy look of the dissipated. But, through all, as I have mentioned, runs the one common feebleness that relates them.

To summarise, probably at least one-third of medical practice is concerned with minor departures from health. Both from the widespread inconvenience that such indispositions give rise to, and from their scientific value, as the starting-points of disease, such borderland phenomena are well worthy of attention. There is here a field for investigation that is a wide and important one, and it is for the general practitioner to cultivate it and bring its richness into the common medical harvest.

THE EARLY DIAGNOSIS AND TREATMENT OF PROGRESSIVE PARALYSIS.

By KARL HEILBRONNER, M.D.,
Professor of Medicine, University of Utrecht.

If in the case of progressive paralysis, which, as experience shows, with all its oscillations and varieties of course leads eventually to death, we may not expect actual recovery, the physician can still by timely interference do much good in the early stages; and, on the other hand, by failing to recognise the disease, the consequences of his sin may be very serious. Very frequently, however, the disease may not be recognised, or it may be recognised too late. The non-recognition of the very earliest stages depends on the very gradual and insidious development of the disease, so that even to the experienced the symptoms become distinct only after a time. But even after this point of time the diagnosis that might be made is not made, partly from want of familiarity with the features of the disease, and partly because the physician really " does not think."

But the designation of the disease, " dementia paralytica," or " progressive paralysis," shows the nature of it—a disease running a progradient course and characterised by dementia and paralytic symptoms, that even, if often, interrupted by remissions frequently lead to death after a few months, but mostly after a few years. Though mainly a disease of the " best years," it attacks men more frequently than women. It only appears on a foundation of syphilis, and its anatomical substratum is a diffuse atrophy in all parts of the central nervous system in varying participation, but without any gross macroscopic lesion.

Dementia and paralytic phenomena are the indispensable symptoms of the disease; but they do not yet justify a diagnosis of paralysis, as other processes also may give rise to the combination, such as typical multiple sclerosis, cerebral tumour, idiocy with paralysis and convulsions, post apoplectic dementia of the aged, intoxication (saturnism, bromism, uræmia, alcoholism), injuries, cysticercus of the brain, a typical multiple sclerosis, many diffuse meningeal tumours, syphilitic meningitides, pachymeningitis. There are also combinations of tabes with diminished psychical activity, which at least practically require a different valuation from the average of paralyses on account of the very slight tendency to progression.

Moreover, in the early stages of the disease by dementia, one must not think of gross insanity. The intellectual failure is of a much slighter grade, and just as little by paralysis does one mean complete paralysis in the usually accepted sense, but rather a more delicate disturbance of innervation.

If the paralysis runs its course purely under the symptoms described, so there is the pure demential form. To this may be associated still other symptoms of any other psychoses (anomalies of affection, delusions, hallucinations). In numerous cases the paralysis runs a purely demential course.

We can divide the somatic symptoms into cerebral and spinal, the latter again into lateral (spastic) and posterior (tabetic).

The symptoms connected with the lateral cœnurus (exaggerated reflexes, hypertonicity, or pareses), especially at the commencement, are not behind those connected with the posterior column in frequency. They must be appraised with caution, however. Simple exaggeration of the patellar reflex is met with in the healthy and in functional disorders. A symmetrical exaggeration is at the most to be taken into account, along with other very suspicious symptoms. The same may be said of the pseudo-clonus that soon passes off and does not always make its appearance, whilst the prolonged ankle clonus, that increases in intensity, and that patellar clonus produced by pushing the patella downwards are characteristic symptoms. Babinski's reflex is also in the latter category, *i.e.*, the typical slow dorsal flexion of the great toe with extension or flat-position of the remaining toes.

The symptoms referable to the posterior column, the tabetic, may be properly divided into two groups. In one the tabes long precedes the other symptoms, and is quickly recognised. More frequently the posterior column symptoms develope only just before the paralytic ones or simultaneously with them. Its symptoms, therefore, do not strike the eye as in old tabelics, but they must be looked for. Testing of sensibility gives with tolerable frequency a " hypalgesia," partly purely of psychical origin, and generally very widely spread; the ataxy is rarely extreme. Romberg's sign (swaying when the eyes are closed and the feet placed together) fails with striking frequency. The attention is to be principally directed to (*a*) The absence of the patellar reflex. Proof of this is difficult in people wanting in intelligence from their straining. One should be careful not to conclude that the reflex is absent when involuntary contraction of the quadriceps prevents its taking place. The attention of the patient must be drawn away from the examination, as his personality increases during it, and he should be asked rather abruptly how he gets on with—his mother-in-law. Simple lessening of the patellar reflex is of importance only when unilateral diminution is constant on one side. The absence of the reflex of the tendo Achillis is less markedly shown, but it is a warning to be cautious, especially if unilateral. (*b*) Pupillary changes. By far the most important disturbance is reflex rigidity (failure to contract on light). It justifies the strongest suspicion of locomotor ataxy or paralysis. Absolute rigidity is more frequently a consequence of syphilis, exceptionally also of trauma or alcoholism. Slow reaction to light is also to be looked upon seriously. Pupillary differences are also frequent in paralysis, but as they are frequent under very various conditions, they are not, when unattended, of much diagnostic value. Pupillary rigidity and loss of the patellar reflex always, therefore, call to mind paralysis or tabes; but it is not by any means the case that every paralytic shows them, and still less every commencing paralytic. (*c*) Hypotone (increased passive movement, especially of the lower extremities) in its lesser degrees is only demonstrable in patients who can easily exclude their voluntary movements. Its value is much increased when associated with considerable increase of the reflexes, or other symptoms of disease of the lateral columns. The cerebral symptoms are in part general (headache, sense of pressure, etc). These have no specific character. For the rest they may be looked upon as expressions of disturbance of definite, cortical, mostly motor lesions. They appear in part insidiously, in part in distinct attacks.

Amongst the first, a change of expression is often a very early sign; without any proper paresis there is a flabbiness and emptiness of the features, which is not fully explainable by dementia. Nearly allied to this is exaggeration in mimicking and clumsiness in carrying out movements; a certain unreadiness in the arms and legs, not altogether explainable by the spinal symptoms, is frequently an early phenomenon. Further than this, paresis of the facial appear early, deviations of the tongue and tremors; but these from the frequency of their occurrence, especially in drinkers, are when alone not of much value.

Disturbances of speech are very early symptoms—symptoms in the strictest sense. Often there is only a certain slowness, often associated with absence of accent, or with it wrongly placed; in other cases the slight precision of innervation leads to mere chattering, to literal paraphrasing, dropping of letters and syllables, turning things over and repetitions, tripping over syllables; something like stammering also takes place.

Where all these component parts are found together, a diagnosis may be formed almost with certainty from the speech alone; but it must be borne in mind that an excited neurasthenic, and especially in presence of the doctor who is examining him, will at times talk queerly—" reel off," as it were. Some of the symptoms are shown off much better in conversation than in special testing, in which, moreover, the celebrated special test words can be well dispensed with, and are often bewildering.

The disturbances in writing correspond in their elements to those of speech, consisting partly in change of the form of the letters, tremor and wandering movements in consequence of motor defective innervation, and in part the same transposing and leaving out of letters as in speech. Only serious disturbances in writing are made evident in short "writing tests." Not infrequently for the rest the handwriting remains good for a very long time.

Amongst the most important of the early symptoms are the attacks of paralysis, as they are often the first occasion for calling in a medical man. But in spite of this, on account of the transient character of the symptoms, their importance is often under-valued. The customary grouping, even if it cannot be carried out in its entirety, distinguishes apoplectiform and epileptiform attacks. The first-named vary between the slightest grades (giddiness, mental confusion) and the severe attacks of loss of consciousness, with succeeding grave unilateral lesions. Serious conditions also that are of almost pathognomonic import as regards paralysis often recede, usually within a few days, leaving only inconsiderable remnants that correspond to the permanent cerebral condition.

The epileptiform attacks in the lightest form appear as localised Jacksonian spasms that leave behind paralysis and paresis. The severest attacks resemble those of genuine epilepsy. The attacks have a great tendency to recur, and even a state of grave status epilepticus is not uncommon.

The dementia of paralysis does not lead at first as such to formal disturbance. What strikes me frequently at first is a defect in the ethical relations, from a slight want of tact to a grosser offence against the proprieties. Neglect of externals, and in regard to clothing, belong to a similar category; further voracity, sudden exaggerated sexuality (often with diminished sexual power), the sudden giving way to alcoholic excess, tendency to sudden outbursts of anger, associated with indifference when more important interests are in danger, caprice, alternating with excessive positiveness.

The intellectual failure in its narrow sense shows itself as deficient comprehension, inability to fix the attention, forgetfulness, want of grasp, imperfect power of combination, inability to recognise familiar faces, defective acquaintance with the elementary details of their own profession. Wherever there is the slightest suspicion of commencing paralysis, cautious inquiry from those connected with the patient should never be delayed as to their normal condition.

Psychotic symptoms in the narrower sense are often absent at the early stage. The commencing paralytic at first does not give the impression of being mentally affected in the vulgar sense of insanity. The most frequent commencing signs are groundless fits of jealousy—an exaggerated sense of well-being, combined with a mania for planning and an impulse to activity, which lead to undertakings that, if carried out, would in an incredibly short time lead to beggary. A similar danger threatens the dementia paralytic through neglecting his business, and, above all, through lavish expenditure.

The graver paralytic psychoses (especially the classic maniacal paralysis) generally belong to later stages. The cases in which the paralysis comes on without specific paralytic prodromata, directly under symptoms of another psychosis, are rare exceptions; they occur more frequently in cases of old locomotor ataxy.

In spite of the review of the features here given, in individual cases the differential diagnosis between paralysis and neurasthenia cannot be made at once, as paralysis may occur in a neurasthenic just as it may in a healthy individual.

On the whole, however, the danger of a mistake is not so great, and the diagnosis of neurasthenia may be determined by exclusion on the basis of repeated careful examination, and after the exclusion of organic mischief. Those cases must be examined with special care—bearing in mind the close connection between syphilis and paralysis—in which a neurasthenic patient has previously been infected with syphilis.

As regards the diagnosis of paralysis as opposed to other organic diseases great caution is required, especially in the case of alcoholics, and further, in old ataxic cases, such a diagnosis can only be deemed certain when unobjectionable cerebral symptoms are present. The examining physician must take care not to speak of the danger of a serious psychosis in the presence of the patient; if the diagnosis is correct it does not do him the least good, if incorrect, incalculable mischief may have been done.

Treatment.—Considering the close connection with syphilis, the question of a course of mercurial treatment first comes up. It has in general proved useless; it is indicated only where specific changes cannot be altogether excluded, and thus in all cases where affection of individual basal nerves is present, small doses of iodides may be given for lengthened periods (sod. iodid 1.0 to 1.5 grm. pro die). From the disappearance of attacks, however, specific disease need not be concluded, as these attacks also disappear spontaneously. The bromides also in large doses, are not very effective in the stages of excitement. In case of sleeplessness prolonged baths at 35 deg. to 36 deg. (cent.) or hypnotics in doses not too small (veronal 0.5 to 0.6 grm. trional 1.0 to 1.5 grm.; paraldehyde 4. grm.; amylhydrates 4. to 5 grm. in a 10 per cent.

aqueous solution, or by enema), and the most prolonged rest in bed.

A special diet is not requisite. A glass of dinner wine, smoking, and the accustomed cup of coffee may be permitted without injury. On the other hand, " going out," from the danger of excesses, should be forbidden. Much more important is the further care for the patient. First of all, when the diagnosis is certain, the physician must draw the attention to those belonging to him to the seriousness of the condition, and with them see about his admission into some institution for seclusion. Such a course is, in almost all paralytics, as a protection, both to the patient (danger of suicide) and his family, absolutely indicated. Only the pure demented torpid forms may seem at first not to demand seclusion. In all cases business activity must be given up at once; a lengthened period of complete mental rest gives some prospect of temporary improvement; but the complete retirement from business best arrests the dangers that the patient, especially when he is in a responsible position, may prepare for himself or for others. Generally the pure demented paralytic adapts himself to the change of giving up business with great nonchalance—the nonchalance itself may afford a final criterion in the differential diagnosis. Business matters will be most safely kept away by putting the patient into an asylum, or some sanatorium for seclusion. Any special methods of treating the basal disease are not possible, even here, but a warning must be given against any energetic hydropathic or any similar procedures.

In the case of any undoubted paralytic who has means or credit, it is advisable to have a trustee appointed as soon as possible. The consequences of insane behaviour may be properly annulled by law, S. 1021, 2 B.G.B. (but this is, unfortunately, frequently not practicable). In answer to the question whether the patient's condition of mental disturbance covered the time when something improper was done, a specimen of the writing of the time in question may be useful.

Regarding the validity of a marriage contracted by a paralytic after the outbreak of the disease, the claims for nullity can be raised according to law, S. 1325, B.G.B. by the legal representative (S. 1336). In the frequent criminal processes against paralytics the application of S. 51 Str. G.B. may be claimed. Very frequently the commission of some illegal act will be the first indication of an onset of the disease. Paralytics are not properly liable to punishment in accordance with law S. 487, Str. Pr. O. If after any condemnation it appears probable, or only suspicious, that the act leading to the punishment was the commencement of a paralysis that only became evident afterwards, it may be desirable, in the interests of the family, to demand a fresh inquiry according to S. 399, 5 Str. P.O. The number of cases in which paralytics are condemned for wrong doings would diminish with increased knowledge and attention to the early stages of the disease.

OPERATING THEATRES.

KINGS' COLLEGE HOSPITAL.

"Hæmorrhagic Necrosis" of Cancellous Bone.—**Mr. Peyton Beale** operated on a man æt. about 35, who had been admitted with the following history: he was by trade a leather dresser, and beyond a few falls from a bicycle had suffered no previous illness or accident of any moment. About five weeks before, he began to complain of severe pain in the lumbar region; the pain was deep-seated and only relieved by the recumbent position; there was no evidence to show that it was in any way due to muscular rheumatism or to his urinary organs, or indeed to any other organs. The pain was soon succeeded by retention of urine followed by incontinence, due to the overflow of the distended bladder; in a few days this was followed by retention of fæces proved to be due to paralysis of the lower bowel; later on incontinence of fæces came on, clearly due to paralysis of the sphincters. He was losing flesh, but was able to walk about until the time of his admission. Upon admission he was found to have: 1. Anæsthesia corresponding to the cutaneous distribution of the left fourth sacral nerve; this anæsthesia extended in some degree down the back of the left thigh, probably corresponding to some cutaneous branches of the small sciatic nerve coming off from the third sacral. 2. Paralysis of the perineal muscles and sphincters and some paresis of the glutei, and perhaps of the hamstrings as well. Upon careful examination under an anæsthetic, a marked swelling of the left erector spinæ in the lumbar region was observed, and on inserting an exploring needle a very little blood-stained fluid was obtained, indicating that this swelling was probably due to œdema of the erector spinæ itself and of the tissues beneath. On examining the rectum a large fluid tumour was felt in front of the sacrum and extending upwards beyond the reach of the finger; this contained loose bodies thought to be pieces of bone, and the case was looked upon as probably one of advanced tuberculous caries of the lower lumber vertebræ involving the lumbo-sacral joint. It was decided to explore the sacrum by operation, and an incision about nine inches long was made over the spines of the lower lumbar vertebræ and back of the sacrum. On separating the muscles from these portions of bone and from part of the posterior aspect of the iliac bones, the whole of the exposed bone appeared dark grey in colour and denuded of periosteum; on cutting through the external shell of compact issue, practically the whole of the cancellous bone was found to be replaced by dark fluid and clotted blood; in many places there were several loose pieces of what appeared to be necrosed cancellous bone. On cutting through the posterior shell of the sacrum there appeared to be nothing left of that bone, and the cavity which had been felt *per rectum* was one containing blood and many pieces of cancellous bone. The membranes of the lower lumbar cord were exposed and incised, and a large quantity (about two ounces) of slightly blood-stained cerebro-spinal fluid escaped. The wound was then closed, a gauge drain having been inserted. Mr. Beale said that until further investigation had been carried out the case could only be described as one of hæmorrhagic necrosis of cancellous bone. The man's symptoms improved for three days after operation, the pain being very much relieved, but on the morning of the fourth day he died very suddenly. A post mortem was subsequently performed, and it was then found that every bit of cancellous bone in connection with the lower part of the spine and the pelvis exhibited the same characteristics as those exposed at the time of operation, viz., "hæmorrhagic necrosis." Professor Dalton, who conducted the post mortem examination, was of opinion that it was probably a case of very extensive myeloma. It may be mentioned that the man was found to have a tumour of the stomach close to the pylorus, which appeared to be a carcinoma, and also some enlarged cervical glands which looked like secondary carcinomatous glands.

Thirty-five cases of bubonic plague have occurred at San Francisco up to date, of which twenty have ended fatally. Twenty suspected cases are under observation.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Sept. 22nd, 1907.

Diazo-reaction of Ehrlich in Eruptive Fevers.

To find the diazo-reaction one should proceed as follows: Pour into a test tube two and a half cubic centimetres of urine, to which is added an equal quantity of the following solution:—

Hydrochloric acid, 50 grammes.
Water, 200 ditto.
Sulphanilic acid (to saturation).

And then two drops of

Nitrate of soda, 0:50 centigrs.
Water, 100 grammes.

That done, the tube is agitated, and ten drops of ammonia are poured in slowly, when a red ring is seen to form at the point where the ammonia comes in contact with the rest of the liquid. After mixing, the red colour is communicated to the entire solution, while the froth resulting from the agitation is of a rose colour, and adheres to the walls of the tube. Such is the reaction in typical cases; that is to say, in eruptive fevers. In normal urine, when tested as above, the colour remains unchanged.

However, certain medical substances, as guaiacol, creosote, benzonaphtol, in being eliminated by the urine, can give a similar reaction. It has nevertheless a certain value for diagnosing such affections as tuberculosis, typhoid fever, and eruptive fevers.

In many cases of typhoid fever the reaction of Ehrlich revealed at the very beginning the nature of the affection, where a positive diagnosis was as yet impossible.

In measles the reaction rarely failed, and before the characteristic eruption had been observed. The colour seems to deepen as the fever increases, and becomes more clear as the temperature falls.

The duration of the reaction is five or six days on an average.

In scarlatina, the reaction is generally negative, as well as in diphtheria.

Sea-Water Treatment.

Injections of sea water, rendered isotonic by dilution with sterilized water, have entered into daily medical practice in France, and notably in Paris, where Dr. Quinton, one of the most ardent partisans of this treatment, has established a dispensary, largely attended by patients suffering from eczema, and children more or less emaciated by chronic gastro-enteritis or suffering from eczema. Chronic constipation has been also treated with success by the saline injections. The doses vary from one drachm to four ounces, and are repeated every two days. The region selected for the injections is generally the scapular, but the abdomen is sometimes preferred.

Apoplexy.

A patient has lost consciousness, the treatment differs according to the cause. Is it a case of coma due to uremia or to diabetes? The diagnosis is not always easy. The antecedents of the patient with signs of diabetes or nephritis that he might have presented, will clear up any doubt. Other affections might be pre-supposed, meningitis, hysteria, syphilis (in a young man), but if the diagnosis inclines to cerebral hemorrhage, the treatment varies with the condition of the patient. If he is pale, with rapid, weak, and irregular pulse, injections of camphorated oil or cafein, followed by a stimulating mixture, if the patient can swallow, constitutes the first treatment, while mustard is applied to the legs and thighs.

More frequently the practitioner will not have to prescribe this treatment, for instead of being pale with a weak pulse, the face of the patient will be congested, and the pulse will be strong and bounding. Here blood letting will be necessary, either directly or by means of ten or twelve leeches placed behind the ears, and the ice-bag placed to the head. A drastic purgative will be prescribed, or an enema, while mustard is applied to the legs.

The following days the purgatives will be continued and a blister applied to the back of the neck.

The consecutive paralysis will be treated towards the tenth day by movements in the articulations, and six weeks afterwards by electricity (galvanic currents).

The diet will be lacto-vegetarian, with suppression of all spirituous liquors. As to iodide of potassium, its action is problematic, and in any case it should be prescribed in only small doses.

GERMANY.

Berlin, Sept. 22nd, 1907.

At the Medizinische Gesellschaft, Hr. Graeffner showed a patient with

Ochronosis,

the first case that had ever been shown in the living. This affection, first described by Virchow, consisted in a brown colouration of the cartilages and skin, occasionally with black patches on the mucous membranes and cornea. Pick had propounded the theory that the affection was the result of chronic carbolic poisoning. In many cases the patients had suffered from chronic ulcers of the legs, and had been treated by dressings of carbolic acid. There were also cases with alkaptonuria in which carbolic acid did not play a part.

Hr. v. Hansemann mentioned a case in which carbolic acid certainly did not play a part. There must therefore be at least two kinds of ochronosis.

Hr. Pick made a distinction between endogenous and exogenous ochronosis. In the latter form carbolic acid was the cause of the pigmentary deposit.

Hr. Orth read a paper on

The Immunization of Guinea-pigs Against Tuberculosis.

He gave an account of his experiments for producing immunization against tuberculosis in guinea-pigs by means of the bacilli of turtle tuberculosis discovered by Friedmann. The animals were first infected with the bacilli of tuberculous turtles; they were then supposed to be in a position to resist tuberculosis from any other source, whether human or any other warm-blooded source.

An animal inoculated with turtle tuberculosis might become diseased, but recover and gain in weight. An animal was so treated, and a year and 12 days afterwards was killed. Tuberculous changes were found on the peritoneum; they had implicated the testicles in which were tuberculous nodules with giant cells; but no tubercle bacilli were discoverable, and even cultures remained sterile. In a second animal, however, into which some of this tuberculous mass was injected subcutaneously, in spite of it appearing well and increasing in weight, on being killed 10 months afterwards, tuberculous changes were found on the peritoneum, and a few baccili were found in the regionary and distant lymph glands which developed sparingly in cultures.

This showed that the bacilli of turtle tuberculosis really belonged to the group of tubercle bacilli; that they were not killed off in the guinea-pigs, but set up a slowly progressing tuberculous affection.

The other animals were infected with human and bovine tuberculosis. All the animals were therefore equally tuberculous, but those with the preparatory treatment lived somewhat longer than the control animals. The mistake was often made of killing the control animals too early. Tuberculosis required time, and results free from objection were only to be obtained if we waited until the animals died. He only killed some of the animals in order to study their condition after infection. In one of the animals that had undergone the preliminary infection, he found a general tuberculous eruption everywhere on the eighteenth day. He observed further that the animals with the preliminary treatment did not get the usual general infection, but only typical pulmonary phthisis with cavities, although they had not lived a long time. The cause of this cavity formation, therefore, did not lie in a lengthened life, but rather in the preliminary treatment.

As Baumgarten and Orth had previously pointed out, these experiments again showed that the lung disease commenced comparatively late. It seemed, therefore, as if the preliminary treatment had a certain influence on the infection with tuberculosis in guinea-pigs, but the result was not great, and further investigations should be made. How this effect, although only slight, was produced, the speaker claimed that it was not due to any weakening of virulence, but by the action of typical antibodies, that acted on the body cells, the action possibly being only explainable from the standpoint of cellular pathology.

Hr. Friedmann believed that with a greater number of animals undergoing the preliminary treatment the results would have been better.

Hr. Wassermann doubted whether immunity could here be spoken of; it seemed more like a super-infection rendered difficult. We knew that if a body had tubercle about it, it was difficult to infect it afresh.

AUSTRIA.

Vienna, Sept. 22nd, 1907.

SWIMMERS AND ALBUMINURIA.

KIENBOCK has recently been watching the constituents of the urine in prize swimmers, and finds that, out of eleven cases, seven of them had albuminuria. The appearance of the albumin is in greatest quantity immediately after a great effort, when an abnormal quantity of waste product is found in the muscles, which produces temporary toxic albuminuria. He attributes this morbid appearance to the exhaustive loss of oxygen in the muscular system that subsequently deprives the kidneys of finally performing the function of normal elimination. In two of these cases there were quantities of sugar. In twelve cases examined for cardiac trouble, seven of them were found with enormously dilated hearts, having arhythmia and murmurs. From these he argues that swimming is an exercise that should be practised with caution, as considerable damage may be done in a subject predisposed to cardiac affection.

TUBAL PREGNANCY WITH MELENA.

Karczewski exhibited to his clinic the left adnexa uteri, right tube with peripheral ends obliterated, and hydatis Morgagni. The middle portion of the tube was dilated, but had normal lumen at the uterine end. The section of the dilated portion revealed a blood clot with a shaggy chorion.

The left adnexa of the left side were dwarfed and deformed. A section of the lumen exhibited ovules in different stages of degeneration.

This was a tubal pregnancy with rupture forming a secondary hæmatocele, which opened into the large intestine. He considered this hæmatocele was the cause of the withering of the right adnexa, the affection of the left being secondary.

The clinical history showed how different the diagnosis becomes with these complications. The woman was only 24 years of age; commenced to menstruate when 14 years old; married at 20; bore one child, everything ending normally, as she had always been healthy and strong. The second pregnancy aborted about the sixth month, after which she lay in bed six weeks. In July, 1905, she was quite well, and had been since her recovery.

On August 8th she complained of headache, pain in right inguinal region, and went to bed. A week after hæmorrhage from the vagina commenced, followed by fibrous masses on the 18th. After this the hæmorrhage continued three weeks, more profuse than ever, but no pain was present.

On September 3rd colic pains suddenly appeared with fainting. A day after she recovered, and was able to move about till the end of September, when she was again attacked with severe pains in the lumbar region, followed by tenesmus alvi, fever, and a discharge of fæces mixed with pus. This continued till she was removed to hospital on October 14th in a critical condition, pulse 100, evening temperature 37.8 Cent., morning 37.2 Cent., abdomen not enlarged but greatly emaciated. Just over the pubis a hard resistance lost in the pelvis could be detected, and with by-manual movement could be detected above and behind the vagina on the left side, while a small round swelling, about the size of an egg, was found on the right in close contact with that on the left. The pus was still present in the fæces, but the rectal speculum gave negative results. The diagnosis was speculative, having something to do with the abortion and presence of pus in fæces. Stupes over abdomen with rectal douches were continued, the temperature standing 38.0 Cent. in the evening and 37.2 Cent. in the morning. On October 20th temperature was normal and patient much better, while the swelling or infiltration seemed less.

On the night of October 27th she took suddenly ill with pain in the bowel followed by a great rush of blood. By the following morning she was white, feeble, and pulseless. In one of the stools there was a litre and a half of coagula.

It was resolved on the 28th to operate, and, making an incision in the linea alba the small tumour in the pelvis with serous contents was found firmly attached to the peritoneum, the latter protruding into the bowel. After enucleation the cyst was removed, and the second hard tumour on the right side, about the size of a goose's egg, was discovered and removed also. The dilated portion of the tube had next to be removed. A clamp centrally admitted of the external portion of the tube being removed from the posterior attachment, when an opening into a clot revealed a large hæmatocele in communication with the bowel.

After securing the internal organs with catgut, a counter opening was made in the pouch of Douglas, the cavity filled with medicated gauze, after washing with a salt solution the whole abdomen was closed. The temperature immediately fell, but rose on the fourth day to 38. Cent., which continued five days. On the ninth day the gauze was removed, and the temperature fell to normal, where it has continued ever since. She was dismissed on the 17th of December perfectly cured.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

PUBLIC HEALTH POSTERS.—The Public Health Committee of the Corporation has ornamented the city with large posters, headed "Diarrhœa" in type almost offensively observable. There follows a quantity of good advice as regards the feeding of children, and the special precautions needed in hot weather. The advice is excellent, but it is to be feared that the last persons to hang about the streets reading the literature provided on advertisement hoardings will be the mothers of the poorer classes. The same advice has been given by the Ulster Hospital for Children and Women for some years past in a much more effective form, as it is printed on a small fly-leaf, and given to mothers in the extern department of the hospital, and distributed through the maternity nurses. It can then be read at home, and referred to in future.

THE WORKHOUSE SANATORIUM FOR CONSUMPTION.—The Abbey Sanatorium, situated about five miles from Belfast, on a fine site overlooking the Lough from its northern shore, was formally opened last week. The house, once the residence of the late Sir Charles Lanyon, F.R.I.B.A., and the beautiful grounds surrounding it, were purchased by the Guardians for the moderate sum of £5,000, and with the house used as an administration block, and new wards built round it, accommodation has been provided for about 250 patients at a cost of £32,000. Additional accommodation can easily be provided in huts in the grounds, which extend to 33 acres. There are at present 120 patients in the sanatorium, and it is hoped eventually to have all the consumptive cases from the Belfast Workhouse removed there.

QUEEN'S COLLEGE: OPENING OF NEW LABORATORIES.—The work of nearly seven years at the Better Equipment Fund saw its full fruition on Friday, September 20th, when no fewer than seven new laboratories were opened at once, an event, according to Lord Kelvin, without precedent in the annals of science.

LETTERS TO THE EDITOR.

THE INEBRIATES' ACT AND THE PREVENTION OF ALCOHOLISM.

To the Editor of The Medical Press and Circular.

Sir,—In the present state of our Parliamentary machinery it seems evident that attempts at paternal legislation are doomed to failure. The House of Commons occupied fully with high politics has not the time or strength to master the minute details upon the understanding of which the construction of effective laws depends. We shall have to wait a long time for the protection of simple people before the fraudulent drink-cure quacks, about whom a correspondent writes in your issue of September 11th, are made amenable to the law; and we shall have to wait perhaps as long before the vendor of fraudulent "nerve tonics" containing alcohol, as well as the whole tribe of bogus cure-mongers of every class, are brought within the reach of the law. Meanwhile the drink traffic under the cloak of medicinal remedies is assuming enormous proportions. The proprietors of one of these baneful drinks are spending at least £10,000 a year in newspaper advertisements alone; and this affords a measure of the vast consumption of these pernicious disguised intoxicants which is going on. The basis of most so-called wine tonics is simply crude alcohol. It would require a clever palate to distinguish the quality of the liquor contained in a mixture of the character of these potions, and there can be no doubt it is spirit of the cheapest kind their vendors can procure. Vast numbers of innocent people who would shrink from over-indulgence in wine are thus led unknowingly to poison themselves with raw spirit; and at least one death from this cause was recently authenticated. Perhaps the greatest evil arising out of this traffic lies in the facilities it affords for secret drinking among women. Of this I could relate many instances. It is very easy for a woman, who would be unable or afraid to send for drink from the usual sources, to order from her chemist a supply of "tonic," and without shame to indulge her craving to the top of her bent.

I am, Sir, yours truly,
Medical Temperance Reformer.
September 20th, 1907.

SPINAL ANALGESIA.

To the Editor of The Medical Press and Circular.

Sir,—I am much interested in Mr. Edred Corner's remarks on the subject of spinal analgesia. There are several points which to my mind require comment and criticism.

1. With regard to the drug used I would point out that novocain is now recognised throughout Germany, and by all those who have had experience of the two drugs (stovain and novocain) as infinitely the better of the two.

Mr. Canny Ryall has pointed out that with novocain there are none of the complications mentioned by Mr. Corner, except headache. After all, what is headache compared to the usual after-effects of any general anæsthetic when given for a period exceeding half an hour?

2. The immense value of spinal analgesia lies in the marvellous freedom from shock even after the severest operations. Mr. Corner does not emphasize this, which is the greatest advantage of this method of obtaining analgesia.

The pulse remains quiet and full throughout the longest operation, and *does not rise afterwards to any extent.*

3. The duration of the analgesia reported by Mr. Corner is very small. It is quite possible, using the proper method, to obtain an analgesia of two hours duration or more.

Mr. Ryall, who is the pioneer of novocain in this country and has used it extensively during the past year, has had uniformly good results.

Dr. P. H. Parsons recently anæsthetised a patient for me with 10 c.c. of a 1 per cent. solution of novocain to which had been added four drops of 1 in 1,000 synthetical supra-renin. This a very small and perfectly safe dose. The patient was suffering from intestinal obstruction, and on opening the abdomen I found a condition of volvulus of the cæcum with a growth involving the posterior wall. I excised the whole of the cæcum and performed anastomosis. The patient did perfectly well; the pulse during and after the operation remained below 100, in fact during the operation did not rise above 70. There was entire absence of shock. Within two days the patient was reading when I went in to see her.

I assisted recently in a Kraske's operation of a severe nature. Here again there was an entire absence of shock. Recently a patient with a fractured olecranon, and also a fractured patella was given chloroform and also ether. By the time the olecranon was wired the anæsthetist decided it would be unwise to prolong the anæsthesia as the patient proved a bad subject for both anæsthetics. The patient was very sick for two days, and was in a more or less delirious state for an equal period. Later he was given an injection of novocain for the patella operation, and this proved most successful. The after effects were practically nil.

In any operation where shock is a factor to be considered this method should be adopted. Its drawback is obviously that the patient knows what is going on, which may be disconcerting to both patient and surgeon, especially if the former is a nervous subject. I maintain that this is the only real drawback; but since it can be prevented by preliminary injections of scopolamine and morphine there can be no question as to the course to pursue in all operations where shock is to be feared or a general anæsthetic is contra-indicated.

I am, Sir, yours truly,
H. Beckett-Overy.

Harley Street, W.,

OBITUARY.

JOSIAH ROBERT JENKINS, M.D.Aber., J.P.

We regret to announce the death at Ruthin, on September 16th, of Dr. Josiah Robert Jenkins, one of the best-known medical practitioners in North Wales. Dr. Jenkins, who had been ailing for some time, was eighty years of age. Until recently he had been the surgeon of Ruthin Prison, and was a justice of the peace for Denbighshire. He also held several other public appointments, and was an ex-Mayor of the town. He leaves a widow, two sons and two daughters to mourn his loss.

JOHN ST. SWITHIN WILDERS, J.P., M.R.C.S., L.S.A.

We regret to record the death of Dr. John St. Swithin Wilders, at his residence, in Birmingham, on September 20th. At one time he took a prominent part in the public life of the city, but for the past 14 years he had been in indifferent health. He was for many years a member of the City Council, a Justice of the Peace, an ardent Conservative, and a pioneer of the Volunteer movement in Birmingham. He studied at Queen's College, Birmingham, and at Paris, and took his diploma as far back as 1858. At the time of his death he was Emeritus Professor of Forensic Medicine at the University of Birmingham, Consulting Surgeon to the Queen's Hospital, the Birmingham Dental Hospital, and the Birmingham and Midland Counties Ear and Throat Hospital.

ARNOLD F. BRADBURY, M.D.Durh., M.R.C.S.

We regret to record that Dr. Arnold Francis Bradbury, of Halifax, died on September 19th from heart disease, at the age of 45 years. As a boy the deceased gentleman became seized with a strong desire to enter the medical profession, and in spite of great obstacles he ultimately succeeded in achieving the object of his ambition. He was educated at Durham University, where he eventually took his M.D. For about fifteen years he practised at Halifax, retiring only a short time since on account of health. He was an ardent Nonconformist, and possessing a kindly nature he was highly esteemed by a large number of friends and acquaintances.

REVIEWS OF BOOKS.

DICTIONARY OF MEDICAL DIAGNOSIS. (*a*)

In these days of bacteriological theories and pathological eccentricities, it is a comfort to turn to a book of good, helpful, healthful clinical observation, well arranged and well written by an experienced physician. Such a book is " A Dictionary of Medical Diagnosis " by Dr. H. L. McKisack, and we commend it without reserve to those who wish either to attain bedside skill or to strengthen their grasp on medicine. It is remarkable for its lucidity of description and its attention to essential detail, no less than for its insistence on guiding principles and its comprehensiveness. Arranged in alphabetical order and supplied with a good index, the work is possessed of such facility of reference as to make the task of handling it a pleasure in itself. Any point can be looked up in a few seconds, and all the needed information found in a reasonable compass. The descriptions are, on the whole, well managed and show the author to be possessed of literary as well as medical skill, and if some are rather bald and unsatisfying, the fact must be attributed to the copiousness of our knowledge of clinical medicine and clinical methods. The article in the examination of the blood is by Dr. Thomas Houston, hæmatologist to the Royal Victoria Hospital, and within the limits to which he is confined he has performed his task well. Similarly a short section on " X-rays in Diagnosis " is from the pen of Dr. J. C. Rankin, physician in charge of the electrical department, and one on " Examination of the Sputum," from that of Dr. J. E. MacIlwaine, medical registrar to the Royal Victoria Hospital. Both give a definite indication of the principles of their subjects, which is as much as could be expected in the number of pages allotted. The illustrations are well-chosen and fairly numerous, the diagrams being especially clear and useful. In every way, indeed, the book may be regarded as one of the best of its kind, and its readers will be amply rewarded by imbibing the enthusiastic and painstaking spirit of the author if by nothing else. Rather more than the proverbial " word of praise " is due to the publishers, Messrs. Baillière, Tindall and Cox, for the get-up and printing of the book are uncommonly good.

ON TREATMENT. (*b*)

DR. HARRY CAMPBELL in his book " On Treatment " has construed the title in such a generous way that everything from medical education to excessive eating, from an account of Dr. Campbell's day to his antics in scaling a 'bus in the rain, are treated of, and a great many other interesting things besides. There was a very popular form of physical competition a few years ago known as the " Go-as-you-please " race, and we are of opinion that some such adjective would aptly denote the nature of this treatise. Not that we complain ; on the contrary, we find it unusually interesting and stimulating, but the title might lead people to expect descriptions of new methods of passing the stomach-tube or the most recent exploits of Teutonic synthetic products. The medical use of the word "treatment" it must be confessed is a specialised and limited one, and the employment of the term in the sense of " discourse " is quite legitimate. The most important point is to discover whether the work is intended for the practitioner, the student, or the public, and here again we were for a time in something of a fix. We thought at first it was for the student, as in the chapter on " Education of the Physician " we seemed to recognise our old friend, the introductory lecture ; but on reaching Chapters VII. and VIII., " On Consultation " and " Quackery," we seemed to have struck a popular harangue ; this supposition was supportable for some time, but Chapter XV., "The Blood-Plasma Therapeutically Considered," finally shattered it, and we were finally reconciled to the " go-as-you-please " theory. Emphasis should be laid on the word " *please*," for the general effect of the perusal of the book is certainly pleasant. Dr. Campbell's ideas and opinions are in the main sensible, orthodox, and reasonable, and if he falls at times into the literary trick of trying to " make a platitude plausible by making it pompous," it is because he is no more than human, and many of the remarks that he makes on well-known subjects are those which he has no choice but to make. Here and there some real " tips " are to be found, and there is a great deal of suggestive value throughout. We must protest, however, in the name of the profession against the doctrine, enunciated under the head of " Humbug," that a physician is ever justified in truckling to falsehood. The truth may be at times suppressed, that is, the physician may say as little as possible on a subject, in the interest of the patient, but the false should never be suggested. Even at the risk of not becoming a " great physician," the medical attendant should establish a character for trustworthiness which nothing can shake. There is a great deal of false sentiment about " breaking " bad news to patients, but apart from any principle, we have never known any real harm accrue from the truth being tactfully put when necessary. Medical men doubtless should always dwell on the bright and hopeful features of a case, and give a patient what heart they can ; but they should remember that the distinction between them and the quack is one of kind and not of degree. Save for this blemish we can heartily commend Dr. Harry Campbell's book to the practitioner in his lighter moments ; it will form a pleasant substitute for a siesta on a Sunday afternoon.

THE DRINK PROBLEM. (*a*)

"THE Drink Problem " belongs to Messrs. Methuen's New Library of Medicine, a series of books on medico-sociological subjects by various authors. Dr. Kelynack, who edits the volume before us, has secured no fewer than fourteen collaborators, and it may be said at once that the value of their contributions is markedly unequal. Some of the sections are exceedingly good, notably, perhaps, those by Dr. William C. Sullivan on the "Criminology of Alcoholism," by Dr. Harry Campbell on the " Evolution of the Alcoholic," and by Dr. Arthur Newsholme on " Alcohol and Public Health " ; some are of average interest and merit, and some—to put it mercifully—appear to have been written in a hurry. On the whole, however, it may be safely asserted that the standard is high ; quite a respectable number of facts are given, theories and remedies are presented very fairly, and the better chapters are free from rant and special pleading. We have to remember, however, that the book is one for the intelligent public, and it is certain that it may have an excellent influence with those who are prepared scientifically to study the subject for themselves, as the dangers and allurements of alcohol are set forth in such a way that a decided opinion may be formed on the facts given. The scientific temperance reformer, unfortunately, generally finds himself in a difficulty when he comes to suggest a remedy—at any rate, any remedy short of prohibition, which is, of course, the logical cure for the evils of drink, and which he recognises to be impossible as the world is constituted at present. The fact is that he does not like to admit the real state of affairs, namely, that under modern conditions of industrial und urban life alcoholic drink is the practical soporific for man's inhumanity to man, and that prohibition would (if carried) create riots to which the agitations of the Corn Laws period would be

(*a*) " A Dictionary of Medical Diagnosis." By Harry Lawrence McKisack, M.D., M.R.C.P., Physician to the Royal Victoria Hospital, Belfast. London: Bailliere, Tindall and Cox, 8 Henrietta Street, Covent Garden. 1907.

(*b*) " On Treatment." By Harry Campbell, M.D., B.S., F.R.C.P., Physician to the North-West London Hospital and to the Hospital for Diseases of the Nervous System. London: Bailliere, Tindall and Cox, 8 Henrietta Street, Covent Garden. 1907.

(*a*) " The Drink Problem by Fourteen Medical Authorities." Edited by T. N. Kelynack, M.D., M.R.C.P., Honorary Secretary to the Society for the Study of Inebriety. Two diagrams. London: Methuen and Co. 7s. 6d. net.

as nothing. It may be taken as axiomatic by all temperance workers that alcohol will be the last evil factor in social life to be removed by reform, and that, hard as it may seem, all legislation and regulations and high licensing are mere momentary symptomatic expedients. Give every man his plot of land, his decent house, his regular work, his games and exercises, and perhaps he will be prepared to renounce his drink; but till then alcohol is the only compensation he has for a life of semi-bondage, often of semi-bestiality, and he will barricade the streets the moment any Government tries to cut his beer off. To pass to another subject, may we implore the editor and his contributor, Mrs. Scharlieb, to abjure that inexpressible vulgarism, the verb "to overlay"? The word, as well as the act it denotes, has come to us from a class which habitually confounds "to lie" with "to lay," in fact, supersedes the use of the former by that of the latter. But that is no reason why we should "paint our mother's cheek," as Professor Clifford Allbutt has it. Still, as has been said, "The Drink Problem," on the whole, is a wise and temperate exposition of a great and many-sided evil; it may safely be placed in the layman's hands as having both good sense, good feeling, and authority.

ALCOHOL AND MANKIND (*a*).

Around the study of man's relation and reaction to alcohol cluster many problems of peculiar intricacy. Many attempts have been made to determine the precise etiology of the human craving for alcohol and the exact action of this chemical agent on animal tissues. The scientific study of alcohol and alcoholism has too often been warped by prejudice or rendered imperfect by the intrusion of moral and emotional or economic and political influences. Since medical writers and investigators have taken up this question as a part of the great medico-sociological study of mankind, order has been brought into a subject where confusion of thought and expression were conspicuous, and rational suggestions for prophylaxis and treatment of alcoholism in its varied forms are now being presented with a scientific precision and calmness which augurs well for the future. Among recent works dealing with the so-called drink problem the monograph prepared by Sir Victor Horsley in collaboration with Dr. Mary Sturge, merits a foremost place. The authors claim to have "put forward the present state of knowledge of alcohol solely on the basis of experimental, anatomical, and statisical evidence," and although they write as convinced abstainers from alcohol their presentation is comprehensive, judicious, and eminently scientific. While no new facts or records of original investigations are noticeable in these pages, the most reliable results of numerous trustworthy observers are conveniently summarised, and the logical and practical conclusions of recent researches clearly enunciated. Medical practitioners will be particularly interested in the opening chapters, which deal with the evolution of medical opinion regarding the value of alcohol as a drug. In a striking diagram it is shown that since 1852 "alcohol and milk have practically changed places as regards the extensiveness of their use." After a brief reference to the chemistry of alcohol and alcoholic beverages and an all too short description of the properties of cell life and the structure of the nervous system, the authors pass to the most serious and valuable sections of their work, a study of the effects of alcohol on intellectual processes and on the various parts of the nervous system. Here will be found reference to the work of such investigators as Kraepelin, Aschaffenburg, Fürer, Kürz, and others. Even when dealing with the terrible effects of alcohol-produced disease and degeneration of the nervous structures, the authors still maintain a strictly temperate and scientific presentation of the case, and in evidence we may quote their concluding remarks in regard to this matter—"alcohol tends to shorten life both by causing widespread degeneration and also by bringing on prematurely the special changes of old age. These changes in the case of the nervous system are, of course, especially to be dreaded because of the accompanying mental deterioration—a deterioration which frequently makes life a misery, and which, at the very least, renders it useless and ineffective."

The physiological and pathological action of alcohol on the other systems of the body also receive attention.

The work is excellently illustrated, and for the coloured lithographs especially much praise is due. In a measure rarely attained in so-called temperance works, pictorial exaggeration has been excluded, and accuracy in details obtained. In the minds of old-fashioned practitioners trained in the ancient days of what may be termed the alcoholic dispensation, and amongst the prejudiced and ignorant in all classes of society, many of the statements and some of the conclusions found in this volume will doubtless be irritably denied or clamorously contended, but at least in the main we have no hesitation in recommending this book as a most reliable and valuable contribution to the scientific study of a subject our attitude to which must in the end be guided and governed by the verdict of science.

The work throughout is written with a simple directness and avoidance of obscurity and redundance which will make it welcome to every intelligent layman. A glossary of technical terms is provided for the non-medical reader.

We trust a copy of this admirable manual may find its way to every medical practitioner and school teacher throughout the land.

ST. THOMAS'S HOSPITAL REPORTS.

The present volume of St. Thomas's Hospital Reports (*a*) is a more bulky volume than any of its recent predecessors, and the increase of size is chiefly due to fuller details being given of the cases which have been treated during the year. The tabulation of cases in the various departments is excellent, and a reader interested in any particular subject has no difficulty in finding his way to the information he desires. The use of the authorised nomenclature for diseases and injuries is to be praised, and we hope to see other hospitals follow in this particular the example of St. Thomas's.

All cases of special interest are detailed with fairly full notes, quite adequately full as regards clinical details. The pathological information is, however, insufficient. This is most noticeable in that part of the surgical report dealing with tumours, and in the *post mortem* records in the medical report. The details given are so few as to be valueless, and one is left in doubt as to the real nature of many of the cases. *Obiter dicta*, such as "carcinoma in some portions distinctly squamous, in others spheroidal" (p. 208), do not elucidate a clinical history. Again, the discovery of "a malignant growth" (nature unstated) in the liver ten years after the removal of the patient's eye for sarcoma, is not sufficient evidence of "recurrence" (p. 91). We would have liked also a little more information on the working of the clinical laboratory. St. Thomas's greatly prides itself on having inaugurated one of the earliest clinical laboratories, and those in charge of clinical laboratories elsewhere are eager to learn from the experience there acquired; the present report devotes exactly one page to the work of the laboratory. On the other hand, the descriptions of the specimens added to the museum are admirably full, and should serve as an example to curators generally. Individual papers on various subjects are contributed by Messrs. Nitch and Corner, and Drs. Dudgeon and Cassidy, while Mr. Robinson writes a graceful memoir of the late Mr. John Croft, who had been on the staff of the hospital for over thirty-five years.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT OBSTETRICAL LITERATURE.

Pyelo-nephritis in Pregnancy.—Fournier (*Zentralbl. für Gynäk.*, Nr. 38, 1907) in a paper on this subject says there are two principal factors to be considered in the causation of this complication of pregnancy. Firstly, compression of the ureters; secondly, descending infection, *e.g.*, bacterium coli and ascending infection, *e.g.*, gonococci, former renal disturbances, and finally congenital malformations of the ureter and pelvis of the kidney. The disease can be divided into two groups:—(1) That produced by the bacterium coli, in which one frequently finds the bacterium in the urine; (2) that produced by the gonococcus, in which the micro-organism is rarely found in the urine. The former is much graver than the latter. The presence of stone in the kidney makes the prognosis more serious. As a rule the prognosis is seldom bad for the mother, but always momentous for the child. Under the influence of proper treatment from the first the disease can improve. Disinfection of the intestinal and urinary systems is the most satisfactory treatment. G.

Premature Detachment of the Normally Situated Placenta.—The most important causes of this according to Gaston (*Zentralbl. für Gynäk.* Nr. 38, 1907) are albumenuria, injury, and endometritis. The most characteristic symptoms are the sudden onset, intense abdominal pain, great hardness of the uterus from tetany, and the abnormal appearance of the uterus which resembles a more advanced period of pregnancy. The prognosis is very bad, both for mother and child. The histological changes to be noted are: In the uterus atrophy of the mucous membrane and degeneration, in the placenta hypertrophy of the decidua, blood clots, alveolar endometritis, which extends over the whole decidual tissue and atelectasis of a great number of villi. When the symptoms are not severe the patient should be kept at rest in bed, labour then usually comes on spontaneously. If the cervix is dilated the membranes must be ruptured and the uterus emptied as soon as possible. If the cervix is not dilated the Champetier bag or Bossi must be employed, or the vaginal cæsarean section if tetany of the cervix be present. G.

Version for Placenta Praevia.—Jolly (*Münchener med. Wochensch.*, 1906, Nr. 25) says in opposition to the more surgical methods of treatment that this remains always the most important means of treating the placenta prævia. The high fœtal mortality is not so much due to the version as to the frequency of debility of the infants since the labour is very often premature. Version may be performed when it is possible to introduce one or two fingers through the cervix. As much liquor amnii as possible should be allowed to escape. The diminution in the uterine contents excites labour, and thus a rapid delivery of the child. G.

The Complications of Septic Abortions, their Ætiology, Treatment, and Prognosis.—Seegert (*Med. Klinik*, 1906, Nr. 31) divides the causes into internal and external. The internal causes being those which by producing intoxication terminate the pregnancy. The external causes are regarded by the author especially as the manifold injuries to which women of the working class are liable during the early months of pregnancy. In cases of feverish abortion, when the cause of the fever is only a decomposition of the uterine contents, the proper treatment is to remove the source of the sapræmia as soon and as carefully as possible, that is, the uterus must be emptied without a sharp spoon or a sharp curette or an ovum forceps. If the internal os is not dilated, laminaria tents or an iodoform gauze tampon in the cervix act quickly and well without producing much injury. If the digital removal of the uterine contents does not produce a cure, and if the bacteria have already extended into the blood or the lymphatic system of the mother, the treatment and prognosis depend on the nature and the virulence of the bacteria, on the action of their products of metabolism, and on the resisting power of the mother. When there is a lymphatic infection a parametritic exudate may arise, or it may result in a phlegmasia alba dolens. With such treatment as opium, heart tonics, cold packing, etc., the prognosis is favourable unless the rare "erysipelas malignum internum" (Virchow) should arise, in which the cellulitis extends into the connective tissue of the trunk. If in cases of infection by the blood stream there should be a rapid invasion of the entire body by pathogenic micro-organisms, this "foudroyant" sepsis has a fatal result in a few days or even hours after the abortion with the symptoms of cardiac paralysis. In cases of septic endocarditis, in which an injury of any sort is not to be discovered in the genital tract, the prognosis remains very doubtful even after complete emptying of the uterus. If the hæmatogenic infection in septic abortion produces a localisation of the bacteria in the ovarian and pelvic veins, the thrombophlebitic form of sepsis or "pyæmia" is the result. Pulmonary embolisms, joint abscesses, infarctions or abscess formation in the kidney (recognised by the bloody urine) show how serious the prognosis is. If the abscesses should be subcutaneous, intramuscular, or periarticular the prognosis is relatively favourable. G.

Cystic Enlargement of the Ovaries in Cases of Hydatidiform Mole.—Goullioud (*Rev. de gyn. et de chir. abdom.*, 1907, No. 1) records the case of a patient, æt. 25, IIpara, who began to bleed about the fifth month of her third pregnancy. On examination two cystic tumours as large as a child's head could be felt, one on either side of the uterus, and both quite mobile. Soon afterwards a hydatidiform mole was born. The convalescence was complicated by phlebitis. Except for some uterine douching and treatment of the phlebitis nothing was done. During this time the tumours began to diminish in size till they gradually returned to the size of normal ovaries. Two years later the woman again became pregnant. The pregnancy advanced normally till the fourth month when abortion occurred. There were no ovarian tumours to be felt. Six months after this she again became pregnant, and went normally to full term without any sign of an ovarian tumour. There was, therefore, in this case a cystic degeneration of the ovaries complicating hydatidiform mole, which would be better called a cystic tumefaction, since the process disappeared and the ovaries returned to their normal size, and were capable of exercising their functions in regard to menstruation and ovulation. Removal of the ovaries therefore in those cases is quite false. G.

Carcinoma of the Ovaries in Cases of Carcinoma of the Stomach, of the Intestine, and of the Bile Ducts.—Goullioud (*Rev. de gyn. et de chir. abdom.*, 1907, No. 2) in a paper on this subject says that malignant tumours of the ovaries frequently complicate cancer of the stomach, intestine, and bile ducts, and are generally bilateral. On the other hand, epithelioma of the ovary may cause metastases in the intestine which resemble primary tumours of the intestine. One must, as a rule, consider malignant tumours of the ovaries as metastases. Therefore in cases of cancer of the pylorus, one must always look for metastases in the ovaries before one decides on operation, and during the operation itself one must never forget to examine the ovaries. In the same manner, when malignant tumours of the ovaries are present the intestines and stomach must be very carefully examined, especially when vomiting and ascites are present. When ovarian tumours are complicated with metastases in the intestines and stomach, although operation should never be shirked, the prognosis must always be regarded as being very doubtful. G.

Fatty Degeneration of the Uterus in Pregnancy.—Ciulla (*Zentralbl. für Gynäk.*, 1907, Nr. 37) in a paper on this subject comes to the following conclusions. From the beginning of the second last month of pregnancy a true fatty degeneration of the uterus exists. This degenerative process falls upon the hyperplastic muscle fibres only. It destroys them, and then produces a fatty infiltration process in the hypertrophic fibres, which in this manner are reduced in bulk so that they may return to their normal shape and size. This fatty degeneration at the end of pregnancy has a moderating effect on the extraordinary irritability of the uterine muscle during pregnancy and also during labour, and we can thus explain in cases of exaggerated degeneration the uterine inertia, and in cases of incompleteness or absence of degeneration the excessive and cramplike contractions which occur during labour. In the same manner we can explain subinvolution and hyperinvolution during the puerperium. We may consider excessive and premature fatty degeneration to be the principal cause of prolonged pregnancy, just as in premature labour there may be an absolute failure of this degenerative process. The fat which is thus derived from the uterine muscle fibres can help to nourish the fœtus during the last two months, and passing into the maternal blood prepares the way for lactation. The fat obtained during active involution is made use of for the milk secretion. G.

RECENT SURGICAL LITERATURE.

The Separation of the Urine of the Two Kidneys.—Luys (*Med. Record*, August 3rd, 1907), the inventor of the Luys' separator, points out the frequent necessity in renal surgery for obtaining the urine of the two kidneys separate. This may be done by ureteral compression, ureteral catheterization or intravesical separation of the urine. Ureteral catheterization has many objections. There is considerable risk of infecting a healthy kidney. It is often untrustworthy as the ureteral sound may not be of proper size, and may slip out; or the ureter may be injured, causing a mistaken diagnosis of hæmaturia, and the kidney may secrete abnormally, due to abnormal excitation. Also the difficulties in ureteral catheterization require considerable experience to overcome them. Endovesical separation of the urine has the following advantages over ureteral catheterization: (1) It is more simple; (2) it may be applied in more cases than ureteral catheterization; it is devoid of danger; the information given by the separator, when properly applied, if possibly not better is at least as exact as that furnished by ureteral catheterization. S.

Perforation of the Gall-Bladder in Typhoid Fever.—Brandon (*Canadian Practitioner and Review*, August, 1907) reports the following case. The patient, female, æt. 18, was being treated for enteric fever which ran a typical course for over three weeks, when one night she was seized with severe pain in the right hypochondiac region. There was considerable tenderness and slight rigidity of the abdominal muscles. Temperature 102°, pulse 120. Perforation was suspected. Fluids were stopped by the mouth, and a hypodermic of morphia relieved the pain. Next morning the abdomen was slightly tympanitic. The pain had descended, and was directly over McBurney's point, and was associated with considerable dulness on percussion, simulating appendical trouble. There were no signs of collapse save the gradual dropping of the temperature and a slight change in the character of the pulse. A diagnosis of perforation in some form was made, either of the cæcum colon or appendix. Operation was decided on, but the patient suddenly collapsed, became pulseless, and soon expired. Post-mortem showed the peritoneal cavity filled with greenish yellow bile. The appendix was small and perfectly normal. The gall-bladder showed two perforations, one the size of the tip of the index finger, and the other that of the little finger. There were also two or three ulcerated patches. In all the literature on this subject there are only thirty-five cases of perforation of the gall-bladder due to enteric fever. Five were operated on, and three of these survived. All the cases not operated on proved fatal. S.

The Treatment of Surgical Tuberculosis by Hyperæmia (Bier—Schmieden, of Bonn *Med. Record*, August 17th, 1907,) points out that Bier's treatment of inflammatory processes increases the normal reaction of the parts, artificially increasing redness, swelling, and heat. It is difficult to arrive at the proper degree of hyperæmia, and it is absolutely wrong to think that if little is good, more is better. A broad (6 c.m.) soft rubber bandage is applied slowly and evenly round the extremity, proximally to, but not too close to the tuberculous joint. Tuberculosis of the wrist joint, for instance, is treated regularly with a bandage above the elbow. Each turn of the bandage overlaps the preceding one. These bandages must not cause pain either at the place of application or in the diseased joint. The extremity below the bandage soon begins to swell in a moderate degree and assumes a bluish red colour. It remains warm, and the pulse remains entirely unchanged. The hyperæmia bandage in tuberculosis is applied only for a few hours per day, and during this time all other bandages are removed, sterilized gauze being placed over discharging fistulæ. The joint is not kept in fixation. The tuberculous joint must be movable after the disease has healed to fulfil the purpose of this treatment. The first result of this treatment is abeyance of pain. Inflammatory contractures also soon disappear, and active as well as passive movements are again possible. Every excessive use of the joint should be avoided. In the further course of the treatment the swelling subsides, large fungous masses are converted into hard connective tissue, which latter, by further treatment, is also absorbed. The contour of the bones becomes visible, tuberculous fistulæ even extending to the joints or bones close. Sometimes with less perfect technique cold abscesses develop. These are never injected with antiseptics, but opened and treated with cupping glasses. Treatment by hyperæmia requires much time, nine months or more in bad joint affections. The treatment is very simple and can soon be applied by the patient himself or by any one who is in the house with him. Almost all cases of joint tuberculosis in Bier's clinic are treated by hyperæmia. It is to be regretted that tuberculosis of the hip joint cannot be treated in the same way. Hyperæmia of the shoulder-joint, however, is practicable. Especially favourable results occur in the ankle, elbow, and wrist. In severe knee-joint disease, where ankylosis has already occurred, resection is practised to shorten the time of treatment. In less severe cases extension and splints are required when the patient is not in bed. The exutative form (hydrops) is never treated by hyperæmia; aspiration, and injection of iodoform emulsion being used. In combination with the elastic bandage cupping glasses are frequently used. They are employed in all cases of beginning softening and of abscesses, which may or may not have fistulous openings. The rarefaction of air is accomplished in smaller cups by a hollow ball, in larger ones by a pump. They are applied intermittently for three-quarters of an hour, being five minutes *in situ*, and three minutes off. A red not a blue hyperæmia is aimed at. By use of the cupping glasses all detritus is evacuated daily through the fistula and hyperæmia of its walls and of the abscess cavity is induced. Hyperæmia is also applicable in tuberculous diseases of the testes, in tendon sheaths, serous membranes, &c. Bier, in the fifth edition of his book, "Hyperæmie als Hielmittel," says: "Formerly I considered the hyperæmic treatment of tuberculosis as good; now I consider it the best." S.

MEDICAL NEWS IN BRIEF.

Maternity Hospital Case.

ADA CHARLOTTE CHOWNE, who wore a nurse's uniform, was indicted at Newington Sessions on September 20th for neglecting three children, named Lena Rivi Murio, Ena Pratt, and Una Edwards, in a manner likely to cause them unnecessary suffering and injury to health.

Counsel said the accused was the matron of an institution described as the Stockwell Maternity Hospital and School of Midwifery, and she had been in the habit of receiving young children to nurse. With regard to the first child the facts were that a young Italian woman, becoming pregnant, her mistress sent her to this institution. The baby was left there, the mistress undertaking to pay 7s. per week. After a time it was proposed to remove the institution to Brixton, and the prisoner asked the mother to take the child away. When the mother did so she found it in a deplorable condition, and her mistress communicated with the Society for the Prevention of Cruelty to Children. An officer of the Society called at the institution and found six children there, although none had been registered under the Infant Life Protection Act. Defendant declared that some of the children belonged to probationer nurses at the hospital. In the case of Ena Pratt, the mother, who had been addicted to drink, had paid the prisoner 19 guineas to be trained as a midwife, but she left the hospital on June 29. Little Ena Pratt was in a dying condition, and the child Edwards was in a state similar to that of Murio.

For the defence it was said the prisoner was a respectable professional woman, who came in for a fortune of £30,000 to £40,000. She married a man who ran through all her money, but she kept to him for the last years of his life. She then associated herself with this "home," which was not a public institution, but a maternity home—a means of earning a livelihood by helping women.

Mrs. Chowne went into the witness-box and emphatically denied the allegations of cruelty. She said that she was fond of children, or she would not have carried on the institution.

Mr. Campbell: But you carried it on for profit?—There was no profit—I only just got a living. Continuing, she said she did not know that under the circumstances she had to register the children.

Evidence was also given that the condition of the children was not due to carelessness or neglect, but the state of their health.

The jury found the prisoner guilty of neglecting the Italian child and Ena Pratt.

Mr. Loveland postponed sentence.

Death Under Anæsthetic.

AT an inquest on September 18th on the body of Reginald Gregory Lund, 46, late of Belmont Mansions, Chelsea, Dr. Stephen Fenwick gave details of an operation which was performed on the deceased, who was suffering from a growth on his tongue. About six weeks previously, at the Charing Cross Hospital, half of the deceased's tongue was removed, together with some glands in the neck. The operation was quite successful, but on September 15th the deceased had again to be operated upon for lockjaw, and he expired while under an anæsthetic. Dr. Fenwick said the deceased had a weak heart, a complaint which was aggravated perhaps by the distress of the operation. Mr. Waterhouse, who performed the operations, said they were successful. The immediate cause of death was heart failure, and the jury returned a verdict to that effect.

Metropolitan Asylums Board.

AN ordinary meeting was held on the 14th inst. at the office of the board, Mr. J. T. Helby, the chairman, presiding. Letters were read from the Local Government Board stating—(*a*) that they were advised that the estimated cost of the proposed additional storage accommodation for coal at the Eastern Hospital was unnecessarily high, and asking the managers to reconsider their proposals with a view to a reduction in the expenditure; and (*b*) that they were prepared to issue an order authorising the proposed expenditure on the goods reception station and porters' lodge at Joyce Green Hospital, but that they were not prepared to sanction so heavy an expenditure as £3,042 on the erection and drainage on the block of eight cottages, and asking the managers to reconsider the matter with a view to a reduction in the cost of that portion of the scheme. Mr. Lower said he was not surprised that the Local Government Board had objected to the proposed expenditure of nearly £400 on each of the cottages. The largest rooms in most of the cottages were less than 11ft. square, and in his opinion they were not worth anything like the proposed amount. The board had been charged by newspaper writers and others with extravagance, and there seemed to be reason for it, because the Local Government Board had constantly to object to their estimates for proposed works. After further discussion, the letters were referred to the Works Committee. The Local Government Board wrote stating that they were prepared to assent to the provision of a central laboratory for the preparation of anti-toxin serum and for bacteriological work, but they would not be prepared to authorise a total expenditure on the works of more than £6,500; and also that they were advised that a saving of not less than £1,000 might be effected by the erection of the laboratory on the Belmont site instead of at Peckham, and they asked the managers to reconsider their proposals in accordance with these views.

Queen's College. Belfast.

THE new laboratories of the Queen's College were opened on Friday last. Considerable disappointment was felt owing to the fact that Lord Kelvin, who had promised to perform the inaugural ceremony, was unable to be present. The laboratories were therefore opened by Sir Otto Jaffe, the chairman of the Better Equipment Fund, and a munificent benefactor to the College, and the address prepared by Lord Kelvin for the occasion was read by his nephew, Mr. James Thompson, himself the son of a former professor in the College. In this address Lord Kelvin traced the evolution of the College from the old Royal Academical Institution, and pointed out plainly that the natural goal is the establishment of an autonomous University in Belfast. Two of the subsequent speakers were in cordial agreement with this weighty opinion, and pressed it home—Sir Christopher Nixon, Vice-Chancellor of the Royal University of Ireland, and Professor Letts, the senior of the science professors in Queen's College. The new buildings may be briefly described as follows:—A series of buildings in the north wing of the College, called the Harland Laboratories, after the late Sir Edward Harland, whose widow contributed largely to their cost, are devoted to physics and engineering. The chemical or Donald Currie Laboratories complete the chemical department of the College, and give every facility, not only for the ordinary practical classes for medical and other students, but also for research work and advanced technical chemistry. The pathological or Musgrave Laboratories have been enlarged by the addition of several new rooms, including one 43 by 28 feet, which forms the professor's private laboratory. In it Professor Symmers rejoices in what he confidently believes is the largest private laboratory in the world, as far as pathology is concerned. There is also a bacteriology room 27 feet square, and a demonstrator's room 22 by 15 feet. The additions to the physiological or Jaffe Laboratories include a practical classroom, fitted with benches having pulleys, shafting, and Kershaw drums for experimental purposes, a practical experimental room, a histology room, a galvanometer room, and a lecture room. To the old medical rooms have been added a large new surgical lecture theatre, with operating table, lift to the basement, preparation room, and many other conveniences for work. The natural history department has also been provided with large biology laboratory, professor's room, photographic room, and botanical glass-house on the roof.

Women Doctors in Austria.

FEMININE ambition has now achieved in Austria a success which is all the more valuable as it has been the object of their aspiration for several years. The Minister of Public Instruction has declared that henceforward girls and women may enter the universities under precisely the same conditions as men, they can give private lectures in clinical hospitals, and be appointed assistants by the professors. The Minister at once granted the first petition of a lady to act as private lecturer and instructor at Vienna University. This lady, Fräulein Dr. Elise Richter, forty years of age, has for the last four years petitioned the professors of the university for permission to lecture upon Roumanian philology. The professors were willing, but the then Minister refused his ratification. The female medical doctors also demanded to be allowed appointments as assistants, and the Ministry caused an inquiry to be made in all the Austrian universities and clinical hospitals. The result of the investigation was that only a few professors opposed the admission of women as private lecturers and assistants, hence the inquiry culminated in to-day's decree by the Minister.

St. Bartholomew's Hospital and Medical School.

During the past year the following changes have taken place in the teaching staff:—

Dr. Christopher Addison, who was formerly Dean of Charing Cross Medical School, and Professor of Anatomy at the University College, Sheffield, has been appointed Lecturer and Senior Demonstrator of Anatomy.

Mr. W. D. Harmer has resigned the Assistant Surgeoncy, and has been appointed Surgeon in charge of the Department for Diseases of the Throat and Nose. Mr. F. A. Rose has been appointed Assistant Surgeon for Diseases of the Throat and Nose. Mr. G. E. Gask has been appointed Assistant Surgeon and Teacher of Clinical Surgery.

Dr. W. S. A. Griffith has been elected Physician Accoucheur with charge of outpatients, and will give part of the Clinical Lectures on Diseases of Women. D. H. Williamson has been elected Assistant Physician Accoucheur and Clinical Lecturer in Midwifery.

Dr. J. A. Willett has been appointed Demonstrator of Midwifery. Mr. C. E. West has been elected Assistant Aural Surgeon. Mr. C. Gordon Watson has been appointed Surgical Registrar, and has resigned the Demonstratorship of Anatomy.

Mr. L. B. Rawling has been appointed Demonstrator of Operative Surgery. Mr. R. C. Ackland has been appointed Dental Surgeon, and Mr. F. Coleman Assistant Dental Surgeon. Mr. R. C. Elmslie has been appointed Demonstrator of Pathology and Dr. H. Pritchard and Mr. H. G. Ball have been elected Junior Demonstrators of Pathology. Dr. H. G. Adamson has been appointed Chief Assistant in the Department for Diseases of the Skin.

Dr. C. M. H. Howell has been elected Junior Demonstrator of Physiology, and Mr. T. S. Lukis and Mr. C. T. Neve have been appointed Assistant Demonstrators of Biology.

The following awards of scholarships and prizes have been made during the year 1906-7:—

Lawrence Scholarship.—G. T. Burke, J. C. Meade (equal). Brackenbury Medical Scholarship.—E. A. Cockayne. Brackenbury Surgical Scholarship.—P. L. Guiseppi. Matthews Duncan Prize.—R. B. S. Sewell. Kirkes Scholarship and Gold Medal.—G. T. Burke. Walsham Prize.—P. L. Guiseppi. Bentley Prize.—H. J. Cates. Hichens Prize.—S. Dixon. Wix Prize.—A. W. J. Cunningham. Senior Scholarship.—A. P. Fry. Junior Scholarship.—R. G. Hill, C. D. Kerr, J. W. Trevan (equal). Sir George Burrows' Prize.—A. W. G. Woodforde. Skynner Prize.—P. L. Guiseppi. Harvey Prize.—K. Bremer. Treasurer's Prize.—R. G. Hill. Foster Prize.—W. C. Dale. Shuter Scholarship.—R. R. Armstrong.

The Report of the Queen's College, Cork.

The annual report of the president of the Queen's College, Cork, for the past year, which has just been issued, refers at some length to the generous offer which was made by Mr. William O'Brien, M.P., of the whole of his own and his wife's fortune, at their death, for the foundation of a local university or for the support of a truly autonomous college, which offer was accompanied by a further suggestion that on certain conditions a sum of £50,000 might be immediately available.

Dr. Windle goes on to say that this generous offer must have great weight with those whose duty it is to consider the proposals which will be made for the modification and improvement of university education in Ireland. He goes on to point out that the expressions of local opinion which he appends proves conclusively the four points which he enunciated in his previous report, and which he now again emphasises:—

(1) That the relations of the college to the district which it is intended to serve have never been satisfactory, and still remain in an unsatisfactory condition.

(2) That until these relations are placed on a satisfactory footing the college cannot expect to have that number of students which, under normal conditions, it would undoubtedly attract.

(3) That such alterations in the constitution of the college as would place it on a satisfactory footing might be made without any difficulty and without any danger to its academic position by alterations in the charter and without direct legislation should His Majesty issue letters making such alterations in the charter.

(4) That there is a great and general desire throughout the whole of Munster that the college should be made available for the people of the province.

Referring to the work of the College during the past session, Dr. Windle says it is more than twenty years since the College has had so many students in attendance, the number being 261, of whom 77 were new students. He records with satisfaction the establishment of a students' club, the work of which has been an unqualified success. A considerable number of other improvements are also mentioned, notably the erection of an operating surgery theatre which in its design imitates the most modern type of operation theatre in a hospital. Many further improvements are, however, needed, and chief among these Dr. Windle puts forward accommodation for the teaching of chemistry and physics.

Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 6, Catherine Street, Strand, London, W.C. There were present: Dr. de Havilland-Hall (in the chair), Dr. F. S. Palmer, Dr. H. A. Sansom, Dr. J. W. Hunt, Dr. M. Greenwood, Dr. W. Knowsley Sibley, Dr. F. J. Allan, Dr. St. Clair B. Shadwell, Mr. H. P. Symonds, Dr. J. Brindley James, and Dr. J. B. Ball. The accounts presented showed that during the first eight months of this year the operations of the Society had been greater than in any similar period of its working. Since January 1st last, nearly nine thousand pounds has been distributed to the members in the shape of weekly sick pay, and good cash bonuses have been given to those who reached the limiting age of 65; yet the funds, which now amount to over £200,000, have received a substantial increase, as the annual income of the Society is considerably larger than its outgo. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

An important concert in the series of twenty Odeon Concerts in aid of the Lord Mayor's Cripples' Fund, and under the Lord Mayor's patronage, was given at Hammersmith Town Hall on Friday, September 20th. Sir John Kirk, the Secretary of the Ragged School Union, again presided, and opened the proceedings with a short speech, pleading very earnestly for the cripples and the cause which the Odeon Company has taken up. The record specially made for these concerts by the Lord Mayor was recited, and could be heard clearly all over the hall.

A scare has been caused at Cleethorpes by a number of people who have eaten potted meat suddenly developing symptoms of irritant poisoning. They are now undergoing treatment. No fatal consequences are anticipated. The whole of one family has been ill, two of the daughters dangerously.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

R. M. P.—The names of the two medical men belonging to the Liverpool School of Tropical Medicine who lost their lives in pursuing scientific work abroad are Dr. Walter Myers and Dr. J. E. Dutton. Dr. Myers died at Para of yellow fever, and Dr. Dutton on the Congo.

Omnibus.—It is not correct to say that the medical officer in question was censured. His abilities were recognised and the smallness of his salary mentioned in such a way that it was clear no extensive duties could have been expected of him. It is unreasonable to suppose that a man, however talented, can do work for which he is not paid, and the more talented men will naturally find freer scope for their abilities in other fields.

Vermin.—There are several preparations of the kind on the market, and we believe they are all of bacteriological origin. They seem all to be harmless, but we are not in a position to say anything positive of our own knowledge; they all have good credentials. You had better write direct to the makers for what they euphemistically term "literature."

Febris.—There is normally a rise in "fever" at this time of year, but the curve for 1907 certainly is higher than for some years past. For the week ending September 7th the number of cases of scarlet fever admitted to hospitals in London rose to 587, as compared with 430, 440, and 557 for the preceding three weeks. Diphtheria and enteric fever showed rather smaller rises.

G. P. I.—The pathology of general paralysis is by no means settled. The theories of Dr. Ford Robertson are by no means accepted by the general body of psychologists. The observations of this gentleman point to there being constantly present certain diphtheroid bacilli in the vessels and affected nervous tissues. He has carried his work to the point of inoculation, and has reported finding like pathological sequelæ in animals.

THE INVENTION OF SPECTACLES.

The invention of spectacles has been attributed to Roger Bacon in the thirteenth century, and also to Alexandro di Spina and Salvino degli Armati, distinguished Italians of the early fourteenth century. These ophthalmic aids, however, are probably of a much older date. Magnifying glasses, at least, must have been in use among the ancients, for it is difficult to believe that the perfection of gem-cutting which they attained could have been acquired without their assistance. The Chinese, too, claim credit for having used them before the Christian era, and the passage in Holy Writ, "Now we see through a glass," is considered by some commentators to be a mis-translation, and should read "through glasses."

W. S. H.—The dates of the various developments are as follows for the infant:—Tears, about the second month; sweat, about the same time; saliva—in any quantity—about the fourth month; appreciation of sights and sounds, about the end of the first week; ability to raise the head, about two months; to sit up, seven months; to stand, twelve months.

R. G. I.—The returns of the Registrar-General for Ireland show a disturbing prevalence of consumption. There were in 1906, 74,427 deaths registered in the country, and of those 11,756—a number equal to 15.8 per cent. of the total—are attributed to tuberculosis. In this respect interest will be found in the comparisons between the death rate from tuberculosis in the three kingdoms between 1864 and 1906. In England and Scotland the returns show decreases from 3.3 to 1.6, and from 3.6 to 2.1 per thousand respectively, but in Ireland there is an increase from 2.4 to 2.7.

Senility.—There are a good many authentic cases of centenarians in this country. Some time ago the case of an old lady who had died in the department of the Haute Garonne, France, at the well-nigh incredible age of 150, who had lived the best part of her life on goat's milk and cheese, was reported. There is also the case of James Grieve, of Ardkinglass, Argyllshire, who is now 107 years of age, and who repudiates what he calls dietetic fads, declaring that he has always been in the habit of eating anything he fancied. At Horncastle, the Rev. Thomas Lord, now in his hundredth year, still occupies the pulpit of his church on Sundays; at Cleeve, Somerset, a well-known resident, Mrs. Honor Coleman, is in her 107th year. Many other instances might be given of centenarians of England, to say nothing of well-known personages like Sir Andrew Lusk and Sir Henry Pitman, whose ages are very little short of five score. Ireland has, in proportion to population, the largest number of aged people. In 1905, the last year for which we have complete returns, seventeen centenarians died in that country in the workhouses alone. The oldest of these, a Limerick man, was no less than 113 years of age.

Anon.—(Imprisonment for Debt.)—Many thanks for the cuttings. We cordially endorse the sentiments.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 2ND.

St. Mary's Hospital Medical School.—3.30 p.m.: Annual Presentation of Prizes and Introductory Address by Professor Osler, M.D., LL.D., F.R.S. 7 p.m.: Annual Dinner of Past and Present Students at the Whitehall Rooms.

WEDNESDAY, SEPTEMBER 25TH.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. L. Mummery: Clinique. (Surgical.)

THURSDAY, SEPTEMBER 26TH.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.)

FRIDAY, SEPTEMBER 27TH.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. S. Stephenson: Clinique. (Eye).

Vacancies.

University of Manchester.—Senior Demonstrator in Physiology. Salary, £150 per annum. Applications to the Registrar.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Physician. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon. Salary, £20, washing allowance £2 10s. with board and residence in the Hospital. Applications to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Assistant Casualty Medical Officer. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications to the Secretary. (See Advt.)

Manchester Royal Infirmary.—Resident Surgical Officer. Salary, £150 per annum, with board and residence. Applications to Walter G. Carnt, General Superintendent and Secretary.

Farringdon General Dispensary, 17 Bartlett's Buildings, Holborn Circus, E.C.—Resident Medical Officer. Salary, £120 per annum, with apartments, coals, gas, and attendance. Applications to the Honorary Secretary.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary, £175 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to the Medical Superintendent.

Metropolitan Borough of St. Marylebone.—Medical Officer of Health. Salary, £600 per annum. Applications to James Wilson, Town Clerk, Town Hall, Marylebone Lane, Oxford Street, W.

Durham County Hospital.—House Surgeon. Salary, £120 per annum, with board and lodging. Applications to Wm. R. Wilson, Secretary, 68½, Sadeler Street, Durham.

Jersey Dispensary.—Resident Medical Officer. Salary, £120 per annum, with furnished quarters and attendance. Applications to the Secretary.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Pathologist. Salary, £105 per annum. Applications to H. Dudley Ryder, Secretary.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C.—Senior House Surgeon. Salary, £100 a year, with board and residence. Applications to the Secretary.

General Hospital, Birmingham.—Two Receiving-Room Officers. Salary, £150 per annum. Applications to Howard J. Collins, House Governor.

Appointments.

De Sylva, E. M. J., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Scalloway District of the county of Shetland.

Foley, Cornelius, L.R.C.P. and S.., L.M.Irel., District Medical Officer by the Ross (Herefordshire) Board of Guardians.

Grandage, William B., M.B., B.C.Cantab., M.R.C.S., L.R.C.P. Lond., Assistant Resident Medical Officer to Queen Charlotte's Lying-in Hospital.

Harvey, Frank, M.R.C.S., L.S.A., District Medical Officer by the St. Columb Major (Cornwall) Board of Guardians.

Henderson, G., M.D.Edin., Certifying Surgeon under the Factory and Workshop Act for the Coldstream District of the county of Berwick.

Imrie, G. J., M.B., M.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Levenwick District of the county of Shetland.

Lavers, Norman, M.D.Brux., M.R.C.S., L.R.C.P.Lond., Physician Superintendent of Bailbrook House, Bath.

Richards, John Barrow Osborne, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer of Health for the Wadebridge (Cornwall) Urban District.

Sharp, P. J., M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Ollaberry District of the county of Shetland.

Skinner, D., L.R.C.P. and S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Lauder District of the county of Berwick.

Births.

Caley.—On Sept. 19th, at 24 Upper Berkeley Street, London, the wife of H. A. Caley, M.D., F.R.C.P., of a son.

Marriages.

Chater—Arnaud.—On Sept. 18th, at the Church of St. Thomas à Becket, Portsmouth, Staff-Surgeon Harold John Chater, R.N., second son of William Chater, Esq., of Godalming, Surrey, to Winifred, youngest daughter of Francis Henry Arnaud, Esq., of Southsea, Hants.

Cowie—Roberts.—On Sept. 19th, at St. Stephen's, Bournemouth, Charles George Cowie, M.A., M.D., of Bon-Accord, Branksome Park, son of the late Alexander Cowie, of Ellon, Aberdeen, to Evelyn Gertrude, second daughter of Fred S. Roberts, of Wyuna, Branksome Park, formerly of Melbourne, Australia.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, OCT. 2, 1907. No. 14

NOTES AND COMMENTS.

Climate and Diarrhœa.

IF anyone doubts that temperature and rainfall are intimately related with mortality, at any rate at this time of the year, the returns for last month as they come in should go a good way towards carrying conviction. The death-rate for this cold, showery summer has been noticeably low, the last two weeks of August only showing 11.5 and 11.8 per thousand as the annual rate of mortality for England, and London for the first eleven weeks of the quarter averaged but 12.0. But with the burst of warm, dry weather that the last three weeks of September have seen, the death-rates have begun to mount again. The great saving, of course, has been in the diarrhœal mortality in young children, which has been almost phenomenally low; certainly so as compared with last year's returns. Now, it is a matter for very serious reflection whether, knowing the outstanding facts, it is not possible from them to construct some working theory. The knowledge that the 4-foot earth thermometer is beginning to rise, and that in due course that rise will be followed by a slaughter of the innocents by diarrhœa, is useless pedantry unless it tends in some way to guide useful action in preventing this lamentable result. It may be argued that temperature and climate are "acts of God," and therefore beyond the scope of preventive medicine, but there is no sense in pursuing the paths of preventive medicine unless attempts are made to circumvent the "acts of God." The factors most needed in the situation at the moment are imagination, and the solid wish to confirm or refute the results of imagination.

The Shortcomings of the Fly.

STARTING with the facts that dry heat in summer conduces to diarrhœa, and that cool showery weather prevents it, and taking it for granted that the cause of diarrhœa is bacterial, it seems necessarily to follow that hot, dry weather conduces to the growth and distribution of the particular bacterial agent or agents at work. Now, the only obvious distributing agencies are the movements of the air carrying particles to a distance, and insects. It is quite a plausible explanation that the rain, falling on successive days during a wet season, lays the dust, and that the dissemination of bacteria is thereby restricted; but it is quite as plausible to argue that cold, wet summers are poor in flies, and that it is to flies we ought to look for an explanation. Probably both factors operate to some extent, but which is the more important, is there not enough evidence to decide? This summer has been markedly poor in house-flies, and we feel our suspicions against them much aroused. That flies can carry infection has been demonstrated, and that they do feed on fæcal matter and on food prepared for human consumption indiscriminately, with, perhaps, a slight preference for the former, is a fact of common observation. We have, then, the following links in the chain of evidence:—That flies can carry infection, that they revel in diarrhœal dejecta, that they frequent food stores, that when they are abundant diarrhœa is abundant, and that when they are absent diarrhœa is infrequent. Moreover, in places where middens exist and sewage disposal is slack, diarrhœa and enteric diseases are generally rife. These facts surely would justify a campaign against flies as vigorous as that against mosquitoes.

Homœopathic Spas.

THE homœopaths, or as we see them frequently styled now the homœpathists, have been disporting themselves at Harrogate. A Congress was held at that town towards the end of last month, and the delegates were refreshed by an address from the President on "Spas I have seen." The "allopathic" infidel is perplexed as to the need for spas in the Hahnemann system, but any qualms that might disturb a doubting brother were speedily put to rest by the president's comforting words. "At first sight," said he, "it might not seem that hydro-therapeutic treatment, either at the spas of Great Britain or on the Continent, have much, if anything, to say to homœopathy. To that he emphatically demurred, because he was of opinion that in the highly varied and luxurious healing founts which nature had caused to flow gently forth from some of the fairest spots on the face of the globe, the alchemy which was connected with the dogma, 'similia similibus curantur,' was distinctly in evidence." "Here's richness," as Mr. Squeers said when he tasted his pupils' milk-and-water. The evidence which supported the alchemy of this dogma was not, as far as we can see, produced; but, then, it is not such an easy task to demonstrate the alchemy connected with a dogma.

Silica in Infinitesimal Doses.

BUT as we read on, we come to even more startling news. "The permanently curative effects of many of these waters, he believed, lay, not so much in the massive doses of the more ordinary salts which they contained, as in the almost infinitesimal quantities of deeply-acting drugs, like bromine, iodine, silica, and arsenic, which also existed in some of them, and very small doses of which we knew perfectly well had a potent and lasting action on the constitution when administered in the dilutions prepared by the chemist. The knowledge of how to use these healing streams was a valuable addition to their armamentarium." The point raised here by Dr. W. T. P. Wolston, in his address, is a valuable one, and may have missed many men's attention. The opinion he gives amounts to this: that things are not what they seem, and that if a patient goes to a spa after a course of free living, and returns home permanently set up, we must not attribute this restoration to massive doses of magnesium and sodium sulphate, but to the cheering and invigorating effect of the infinitesimal quantities of such "deeply-acting" drugs as silica. In the midst of the material world of medicine, how refreshing it is to have these idealistic conceptions to counteract the hard facts of science and experience!

The "Art and Mystery."

A subsequent speaker at the same Congress made the apposite statement that "homœopathy was like Christianity in one respect—it contained both truth and mystery. That there was truth in it they all knew, and the mystery that attached to it was the mystery that led to everlasting discussion." We do not remember to have heard the homœopathic position stated with quite so much candour before. The great difference between Christianity and homœopathy, we should think, would be that Christianity contained a great deal of truth to a little mystery, while homœopathy contains very little truth to a great deal of mystery—resembles, indeed, Falstaff's hotel bill in containing but "one halfpennyworth of bread to this intolerable deal of sack." But, as the Congress speaker said, it is this mystery which leads to everlasting discussion, and we might add that it is just this "mystery" which attracts a certain class of mind which has not the openness to prefer demonstration to speculation. The beauty of the everlasting discussion that ranges about homœopathy is that, like the disputes of the old schoolman, it can lead to no useful result, and the point at issue remains as obscure and mysterious after the argument is over as when it began.

The Boot on the Other Foot.

The firm known as "Boots, Cash Chemists, Ltd.," which combines the useful art of pharmacy with the vending of trinkets and the circulation of literature, were considerably perturbed the other day by being summoned for the offence of selling tablets containing strychnine without the precautions enjoined by the Pharmacy Act. The offence was proved by the Pharmaceutical Society, who initiated the prosecution, and the defendants fined. By way of justifying themselves, Messrs. Boots proceeded to summons a qualified pharmacist, trading as W. Walter Madden and Madden and Co., for a similar fault, and at Westminster Police Court, on September 23rd, they succeeded in getting a conviction. To the medical man this occurrence suggests several lessons. In the first place, everyone must regret the decline of the old-fashioned pharmaceutical chemist who was in business for himself, had one shop, and personally supervised and was responsible for everything that went on therein. In the second place, there must be equal regret for the unhappy habit that is springing up of indiscriminately selling to the public any drug that is asked for. And, thirdly, it seems that the restrictions of the Pharmacy Acts, little effective as they are, can be easily neglected. Happily, it is still possible for medical men, by recommendation and patronage, to support those pharmaceutical chemists who give their personal attention to their business, and conduct it with a due sense of its grave obligations.

LEADING ARTICLE.

PLURALITY OF HOSPITAL APPOINTMENTS.

The honorary medical staff of the Bristol Infirmary have found themselves suddenly plunged into the throes of a controversy with their Board on questions connected with the terms of their appointment. The issues involved are of the deepest interest to the medical profession generally, and on that ground claim an amount of attention not usually accorded to a local hospital dispute. The crux of the matter may be readily gathered from the two following rules which were last week passed at the half-yearly meeting of the Royal Infirmary Board by about twenty out of seventy-two governors. The new rules provide that: "No member of the honorary staff shall hold any union or club appointment. No member of the full staff shall hold any other professional public appointments other than a professorship or lectureship at any university, college, or school. No member of the assistant staff shall hold any other general hospital appointment, nor more than one special hospital appointment. That the full physicians shall limit their practice to medical work. That the full surgeons shall limit their practice to surgical work. That each of the specialists shall limit his practice to his speciality." The new rules, therefore, involve two points—namely, plurality of appointments and the ethics of consultant and specialist practice. With regard to the first, it is not easy to understand why, in a provincial town like Bristol, the Committee of the Infirmary should take so sudden a stand against plurality. There is a large general hospital, but the posts there are never held in common with those at the infirmary. There are the usual number of small medical charities, general and special, that we would expect to find in a population of some 320,000. Within a generation the ancient city of Bristol has greatly increased in size, probably by one-third. The medical school is one of old standing, and many famous medical men have been connected with the Royal Infirmary at Bristol. Of late years the local school has entered on a new phase of existence by its absorption in the Medical Faculty of the Bristol University. It may be that these altered conditions may demand the framing of fresh ethical rules on the part of the profession and of alterations in the tenure of appointments on the part of the executive boards of the medical charities. The new rules were energetically upheld by the President of the Infirmary, Sir George White, who quoted a series of rules against plural appointments in force at hospitals and infirmaries in Birmingham, Leeds, Liverpool, and Manchester. The populations, and consequently the number of medical charities, however, of those towns vary from 450,000 in Leeds to 650,000 in Manchester, and they can hardly be regarded, therefore, as parallel instances. As regards the general question of multiplicity of hospital appointments, it may be pointed out that there is pluralism and pluralism. There is the tenure of two, or in some cases three, posts that are well within the capacity of a single individual, with work that extends the experience and strengthens the capacity of the holder. Especially true is this of the holding of an appointment in some special branch in addition to a general post as physician or surgeon. In Bristol there seems little chance of any man holding so many posts as to be incompatible with the proper discharge of his duties. Were there any such risk, it would be easier to understand the sudden reversal in the policy of the infirmary, which has hitherto given a free hand to its medical staff to hold what outside posts they wished, and to do consultant, general, or special practice as they chose. As regards the holding of multiple posts by one man who is obviously unable to do his duty in all of them, we hold that kind of pluralist as an anachronism and a hindrance to his profession. His existence handicaps most unfairly the career of many a promising young man, who is thereby prevented from entering the lists. So far as the restricted and wholesome plurality that is likely to obtain in Bristol is concerned, we are absolutely in agreement with the local medical men, who regard the matter as one that concerns themselves alone. We venture to hope that the new rules will be reconsidered by the whole body of governors of the infirmary. At the same time, we suggest that the resolution to restrict the private medical practice with certain conditions should also be reconsidered. During a long and not undistinguished history, the Royal Infirmary has been well and ably served by men who were for the most part frankly engaged in general practice. There is much to be said for a system of that kind, which reduces the doctrines of advanced science to the test of daily and sustained application. In the past, at any rate, Bristol has had no reason to regret the service of her medical charities by medical men engaged in general practice. Whatever the upshot of this new departure on the part of the Royal Infirmary, we trust that the decision will be submitted to the whole body of the governors, and that the views of the local medical profession will be duly considered.

CURRENT TOPICS.

The Beatitude of Bowls.

THE twentieth century has been ushered into existence in the midst of a kind of athletic renaissance among the nations of the earth. Cricket, football, rowing, tennis, cycling, golf, all have their devotees; while recreations demanding varying degrees of strength, skill, and activity are hardly less popular. One of the most recent revivals is the ancient game of bowls, which now bids fair to take once again a leading place among the sports of Merrie England. As a matter of fact, it is just as good a game to-day as it was in the time of Raleigh or in the remote Anglo-Saxon times. While it provides good, easy exercise for the whole body, it requires a moderate amount of skill, without laying too great a strain upon the mind. The whole environment of bowls is restful; its green sward a delight; its battles one long, enthralling beatitude. Not least of all, it is within the power of man, woman, and child to play a fairly good game, although the higher flights demand a level of achievement that is undreamed of save in the house of the serious player. So that it may pretty safely be assumed that bowls will once again take a foremost place amongst our national games. From a medical point of view, we have nothing but praise for this most excellent of recreations. It provides open-air exercise and amusement for old and young, it is admirably fitted for many invalids, and, above all, it is one of the best of what may be called natural opiates.

Scarlet Fever and Sanitary Science.

SCARLET fever still presents an unbroken front to the attacks of the sanitarian. In spite of many years of notification and the enormous sums that have been expended in the hospital isolation of the malady, there is no sign of decrease in its annual incidence upon the nation. Nor is it at all hopeful under present conditions that scarlatina will ever be exterminated by sanitary measures alone. Its short incubation, its high degree of infectiveness, and its proneness to attack infancy and childhood, render it one of the most difficult of all the specific fevers to bring under control. Indeed, the prevalence of scarlet fever in most of our great towns at the present moment is such as to constitute an admitted failure of the measures of public health hitherto organised with a view of controlling and ultimately eradicating the disease. Some day the key to the position may be placed in the hand of medical science, which has solved many problems of no less apparent hopelessness. Take the case of cholera and of small-pox, for instance; one has been banished altogether from our shores, and the other has been reduced to a fractional and feeble existence. On the whole, it seems possible that the future control of scarlet fever may be in the direction of some preventive vaccine or serum. Why should not the Government find the money to carry out an authoritative scientific investigation upon this point? At any rate, it seems clear that our present public health methods in dealing with scarlet fever stand in need of revision.

School Hygiene.

AN important divergence of views has taken place with regard to Dr. George Newman's appointment as Chief Medical Officer to the Education Board. It is held that the post should have gone to Dr. Kerr, of the London County Council. As both these gentlemen are of high position and ability, the matter might seem to be merely a personal one, but this is not the case. The question at issue is really the vitally important one as to whether the administration of hygiene in schools shall take place through the ordinary sanitary machinery of local authorities, or whether school hygiene shall be totally separated from ordinary public health work and managed by a distinct staff. The decision on this point was practically made by the late Government when it did away with school boards and made county councils and municipal authorities responsible for education. Had the old school boards remained, no doubt it would have been comparatively easy to make each authority responsible for the respective interests; but the matter is so complicated now by the fusion of education with municipal affairs, that the distinction of sanitary administration from school hygiene administration would be difficult to maintain. Sir Robert Morant, Permanent Secretary to the Education Board, had apparently decided that the medical inspection of schools should take place through the channels of the departments of the medical officer of health, and therefore the appointment of a medical officer of health, pure and simple, to be head of the medical department of the Education Board was natural, and a sound and well-known man was selected for the post. Whether this policy is the right one is a weighty question which deserves full discussion.

Mental Condition of Rayner.

The view expressed in the Medical Press and Circular at the time of the trial of Horace G. Rayner for the murder of Mr. Whiteley—namely, that the man was not mentally responsible at the time of the crime—has been strikingly confirmed by the latest news from Parkhurst Prison, where he is now incarcerated. It is reported that Rayner is now recognised as being in a hopeless mental condition. His suicidal intention shows no tendency to diminish, and after a probationary period of "observation" he has been classified by the medical staff of the prison as permanently weak-minded. It is no longer considered safe to confine him in a separate cell, even under close observation. He has accordingly been transferred into an "association ward," where a warder and an orderly are in constant attendance. Ever since Rayner's reception at Parkhurst he has been in hospital, and he is likely to remain there until released by death or transferred on certificate to a criminal lunatic asylum.

The Anti-Vivisection Hospital and the Sunday Fund.

That curious product of modern medical evolution, the National Anti-Vivisectionist Hospital at Battersea, is clearly not going to take "lying down" the refusal of the Metropolitan Hospital Sunday Fund to make a grant. Their secretary has been engaged in a fulminating correspondence with Sir E. H. Currie. The latter gentleman has been indiscreet enough to state in reply that the governing body of the Battersea Institution imposes restrictions on its medical staff. The Hospital Sunday Fund, he adds, can in no case assist institutions whose governing body dictates the form of treatment to be used by the medical staff. To that statement the secretary promptly replied, pointing out that, whereas the Homœopathic and the Temperance Hospitals imposed special forms of treatment upon their medical staff, both of them received grants from the Sunday Fund. Logically, the position appears to be unanswerable. A fundamental rule of administration, the first we remember to have heard from the Hospital Sunday Fund, is laid down by a responsible official, but is at once shown to be unequally applied. We have no sympathy with the supporters of the Anti-Vivisectionist Hospital authorities; on the contrary, we regard their views as narrow, illogical, and ludicrously disingenuous, but nevertheless we think that institution is entitled to fair treatment. If they are excluded from a grant by a law that is only applied in particular instances, then they are unjustly dealt with. The weak point seems to be the want of a declared policy by the Metropolitan Hospital Sunday Fund, which is now enabled to inflict a serious injury upon a medical charity by withholding a grant on grounds that are, as a rule, autocratic and absolutely secret.

The "Fainting Fit" in Criminal Assault.

Of all classes of criminal inquiry, there is none that should be approached with more caution and calm judicial alertness than that which deals with sexual charges. The very fact that such cases are generally heard *in camerâ* renders paramount the necessity of an absolutely impartial administration of justice. The criminal assault, by the very circumstances of the case, furnishes a readily available instrument to the hand of the blackmailer. Short of that, it suggests itself automatically, as it were, to the disturbed imagination of the hysterical or the epileptic woman, who often believes implicitly in the reality of her imaginings. Again and again the apparent sincerity of her evidence may convince a seasoned court of justice. Members of the medical profession are always specially open to the charges of blackmailers or of hysterical women. Only last week a medical practitioner in the East of London was tried at the Central Criminal Court on a charge of assault on a young married woman. In her evidence she stated that, being subject to fainting fits, she went into one of them, and on coming to found herself on a sofa and prisoner assaulting her. A "fainting fit" of this kind is of so peculiar a type as to be in the highest degree unlikely and suspicious. As a matter of fact, the judge, acting on the opinion of the jury, very properly dismissed the case.

Medical Officers of Health and Security of Tenure.

The last thing that is likely to be learnt with regard to the origin of many public disputes is the truth of the matter. As regards Southend it has been more than hinted in some quarters that Dr. Nash has been deprived of his post as Medical Officer of Health because of his zeal in public sanitary administration. Whatever may have happened in his particular case, there can be little doubt that the general question as to the permanency of health appointments of that kind is in urgent need of authoritative discussion. Under the present system, as we have for many years past pointed out in the pages of the Medical Press and Circular, the annual election, or the power to dismiss a Medical Officer of Health without the sanction of the Local Government Board, opens the road to many abuses. A competent and zealous official in that capacity must necessarily come more or less into collision with members of the Council which he serves. At every turn he finds himself called upon to criticise his own masters, who as tradesmen, landlords, and so on, are continually brought into contact with the Public Health Acts. A man cannot act satisfactorily as servant and judge upon the councillors; even if he have the will the councillors will take good care that he has not the way—at any rate after the next succeeding election.

Sheffield Infirmary Trouble.

At present the position at Sheffield, from the spectacular point of view at all events, is one of marking time. The Hospital Committee are preparing a scheme for presentation by the Board of Guardians at their next meeting, and the medical men of the district have met and passed resolutions to the effect that they consider the arrangements at present in force unworkable, and that they do not see that they are called upon to take any active steps in the matter. By a curious coincidence, however, two Local Government Board inspectors, Dr. Fuller and Mr. Bagenal, have visited the town and held a consultation with the Hospital Committee. In an inspired paragraph in the *Sheffield Daily Telegraph*, it is stated that this visit had no connection with the dispute in hand, but was connected with a suggested amendment of the Hospital Separation Order, which, it is naïvely asserted, does "indirectly" affect the issue. Moreover, the Hospital Committee, says the paragraph, incidentally informed the inspectors of the new scheme. From the line the Local Government Board has always hitherto taken in matters of this sort, we have little doubt that proper advice was given to the Hospital Committee, and though perhaps the inspectors could not take official cognisance of the embryo proposals, our forecast would be that a deft finger was laid on any objectionable points. If the matter is satisfactorily adjusted, we cannot grumble, perhaps, at the Guardians wishing to save their face.

Register! Register! Register!

The usual appeal has been made by the General Medical Council to members of the medical profession to notify any change of address to the official headquarters at 299, Oxford Street, London, W. In view of the somewhat unbusinesslike character that is often attributed to the profession in question, it may be well to remind any of our readers who may have changed their residence during the year that the omission to notify the same may possibly lead to a removal of that individual's name from the "Register," with the consequent inconvenience and annoyance of such a position. The Registrar also adds, significantly, that much trouble will be saved if the names are written clearly, and the full names, or, at least, the full initials, be also given.

PERSONAL.

Dr. James Craig will deliver an address at the opening meeting of the medical session at the Meath Hospital, Dublin.

A fountain, in memory of Dr. James Wilson, of Govan, was unveiled in that town last week by Mr. Robert Duncan, M.P.

Mr. R. F. Tobin, F.R.C.S., delivered on Tuesday last an address introductory to the medical session at St. Vincent's Hospital, Dublin.

Dr. Reginald Stilwell will entertain the members of the South-Eastern Division of the Medico-Psychological Society for their autumn meeting at Hillingdon.

We beg to congratulate Dr. French of the White Star liner, *Majestic*, on his providential delivery from a murderous attack by a lunatic on the ship.

The International Congress of Hygiene and Demography was opened on the 23rd ult. at Berlin by the President, Prince von Schoenaich-Carolath.

Dr. M. Grabham, representing the Royal College of Physicians of London, gave an address at the centenary of the Geological Society on September 26th.

Dr. F. M. Sandwith, Gresham professor of Medicine, will give the first Hunterian lecture of the Hunterian Society on October 9th, at 8.30 p.m., on "Dysentery."

Dr. A. E. Garrod will open the winter session at the Hospital for Sick Children, Great Ormond Street, London, by a lecture on October 10th on "Diabetes in Children."

Mr. T. Neville, L.R.C.P. and S.I., of Goelen, co. Cork, has been the recipient of a handsome suite of hall furniture on the occasion of his wedding, presented by the inhabitants of Goleen.

Dr. James Rutherford has resigned his post as Medical Superintendent of the Crichton Royal Institution, Dumfries, on the ground of ill-health. Dr. Rutherford has held the post for twenty-four years.

Sir Lauder Brunton has been compelled to undergo an operation in the Royal Victoria Hospital, Montreal, but we are pleased to hear that his homeward journey is not likely to be delayed for more than ten days or so.

Mr. James Carroll, surgeon in the United States Army, has recently died after prolonged suffering, as the result of contracting yellow fever from the bite of a mosquito, which he allowed to bite him for experimental purposes when investigating the disease.

The British delegates to the Berlin Congress for Hygiene included Dr. Whitelegge, C.B., His Majesty's Chief Inspector of Factories and Workshops, and representatives of the War Office, the Admiralty, the Local Government Boards of England and Scotland, and the Board of Education.

Mr. Charles Sissmore Tomes, M.A., F.R.S., F.R.C.S., who delivered the inaugural address of the Manchester Medical School on the 1st of October, is Treasurer of the General Medical Council and Vice-President of the Zoological Society. His subject was "Medicine and its Specialities and the State: a Retrospect and a Prospect."

Dr. W. Hale White will deliver the opening lecture of the winter session of the North-East London Post-Graduate College and of the North-East London Clinical Society to-morrow (Thursday), at 4 p.m., at the Prince of Wales's General Hospital, Tottenham, the subject being "The Various Conditions Causing Enlargement of the Liver." All qualified medical practitioners are invited.

It is stated that the selection committee of the Unionist majority in the Liverpool City Council has unanimously recommended Dr. Richard Caton for election to the position of Lord Mayor of the city for next year. He is a member of the Liverpool University Council and of the General Medical Council.

We are glad to announce that on September 26th Dr. J. M. Rhodes was honoured by a presentation at Didsbury. The presentation took the form of a cheque and an illuminated address, to which there were 250 signatories, and the subscribers to the testimonial included all classes of the community.

The following gentlemen have lately been the recipients of presentations from patients, friends, and institutions they have served for long periods of time. Mr. William Annesley Eden, L.R.C.P. Lond., M.R.C.S.Eng., on the occasion of his leaving Wadebridge (Cornwall); Mr. Frederick Weatherby, M.R.C.S.Eng., L.S.A., J.P., after more than twenty-five years' service to local public institutions at Long Ashton (Somerset); and Mr. Eleazar Davies, L.R.C.P. and S.Ed., at Pantywaun, near Dowlais.

A CLINICAL LECTURE
ON
CONGENITAL ANOMALIES OF THE EYE. (a)

By SYDNEY STEPHENSON, M.B., F.R.C.S.Ed.,

Ophthalmic Surgeon to the Kensington General Hospital, the Evelina Hospital, the North-Eastern Hospital for Children, etc.

(Concluded.)

III.—Anomalies Due to Intra-Uterine Inflammation.

Considerable attention has recently been paid, especially on the Continent, to intra-uterine inflammation and infection as factors in the causation of certain anomalies of the eye. It is, indeed, difficult to account for some conditions, as congenital ophthalmia and congenital staphyloma, on any other grounds.

In the first case, a few words may be said with regard to so-called "congenital ophthalmia," as to the existence of which there can be no shadow of doubt. That babies might be born with ophthalmia is a fact that has been known, although perhaps not generally recognised, for many years. The existence of such cases was alluded to by Quellmalz in 1750. In 1902 Dr. Queirel, a Marseilles obstetrician, whose work apparently has been overlooked by ophthalmic surgeons, reported 15 cases of the kind that he had observed in the course of his work (*Leçons de Clinique Obstétricale*, 1902). I have recently collected from the literature 71 cases of ante-partum ophthalmia, and to that number have been able to add 19 others met with in the course of my own work. The material at hand, therefore, amounts to 105 cases, a number that shows pretty conclusively that this form of disease is nothing like so rare as has been assumed.

In explanation of the cases it has been very generally assumed that the liquor amnii had been discharged long enough before the completion of the second stage of labour to allow of inoculation of the infant's eyes by gonococci or other organisms present in the maternal passages. Assuming that the fluid was really liquor amnii, and not liquid such as is known to be now and then present between amnion and chorion, this premature escape doubtless accounts for a moiety of the cases. It may actually have taken place in 26 of the 71 cases where the time of rupture of the membranes was mentioned. There still remain, however, 63.38 per cent. of the cases in which this view, known as Haussmann's, does not apply. The bacterioscopic examination of the discharge from the eye gives us no help, since the results do not differ markedly from those obtained from ordinary cases of ophthalmia neonatorum. Thus, among my 19 cases, gonococci were present in 52 per cent., pneumococci in 10 per cent., bacterium coli in 5 per cent., B. pyocyaneus in 5 per cent., and the results were negative in 26 per cent. Thanks to the work of Kühne, Haussmann, and recently of Hellendahl (*Beitrage zur Geburtshilfe u. Gynak.*, Band X., Heft 2), there is now experimental evidence to show that penetration of the intact amnion by bacteria is possible. It is known that organisms, especially the gonococcus, may lurk in the recesses of the uterine mucosa, and it seems likely that they may pass through the chorion and amnion, and thus reach the liquor amnii, where they infect the conjunctival sac during the last weeks of pregnancy—that is to say, at a time when the eyelids are no longer closed, as at an earlier period in fœtal life. What is true of the gonococcus is true also of the other micro-organisms found in association with ophthalmia neonatorum. The bacteriological permeability of the membranes once granted, organisms may reach the uterine cavity either from the mother's anus or from the peritoneum *viâ* the Fallopian tubes.

The etiological analogy of ante-partum ophthalmia with the condition in which the liquor amnii is occasionally found to be brownish in colour, muddy in consistence, and peculiarly offensive to the sense of smell, is somewhat striking. The fluid in these cases may be likened to an ordinary typhoid stool. Indeed, the two conditions—ophthalmia and offensive liquor amnii—have been known to co-exist, as in cases reported by Chavanne (*Rev. Générale d'Ophtalmologie*, 1899, p. 70), and by Armaignac (*Annales d'Oculistique*, 1902, T. 128, p. 241). Dr. Handfield-Jones has recently published (*Journ. of Obstet. and Gyn of the British Empire*, April, 1907, p. 305) five of these cases observed among 3,300 deliveries at the British Lying-In Hospital, London. In one case, examined bacteriologically, the stinking liquor amnii was found to contain staphylococci and coliform bacilli. Handfield-Jones thinks that if infection with the coliform bacillus occurred after rupture of the membranes, then the putrefactive changes must have supervened with preternatural rapidity. In one of his cases, however, the amniotic fluid was noted to be muddy and offensive at the time the membranes ruptured.

The etiology of ante-partum ophthalmia has been discussed at some length, because it forms an authentic and comparatively simple instance of intra-uterine infection, and renders it more easy to understand what may occur in other cases believed to be due to the same cause, such as congenital adherent leucoma and staphyloma, and dacryocystitis, and opacities of the cornea, and the rare and curious conditions called "cryptophthalmia" and "buphthalmia."

Congenital Staphyloma.—This rare condition, of which only about twenty cases have yet been published, is almost certainly due to perforation of the fœtal cornea, as the result of intra-uterine inflammation. This view has been strongly urged in an important communication on the subject by Mr. J. H. Parsons (*Trans. Ophthalmological Society*, Vol. XXIV., 1904, p. 47), who bases his opinion to a large extent upon the histological appearances presented by such an eyeball removed from a child aged three days. As Parsons points out, "All these cases of anterior staphyloma show exactly the same features as those found when the condition develops in the usual manner after birth." "*A priori*, therefore," he continues, "we should naturally be inclined to attribute them to the same cause." The considerations that apply to congenital staphyloma apply equally to an even rarer condition—namely, *congenital leucoma adherens*—that is to say, a corneal cicatrix to the hinder surface of which the iris is adherent.

Congenital Dacrocystitis.—Although, as explained before, the essential cause of this condition is undoubtedly of a developmental nature, yet when a baby is born suffering from a suppurating or distended lacrymal sac—from a lacrymal abscess, in fact—the infection must have taken place prior to birth. The organisms present in such cases are the pneumococcus, the bacillus coli, the common pyococci, and the xerosis bacilli, of which all, with the possible exception of the xerosis bacillus, have been found in the genital tract of parturient and puerperal women. It is probable that in these cases, as in many of congenital ophthalmia, the micro-organisms gain access to the epithelial *débris* of the lacrymal passages by passing through the unbroken fœtal membranes, and that they reach the cavity of the uterus either by ascending from the pudenda or by descending by the Fallopian tubes.

Congenital Opacities of the Cornea.—In rare cases a child is born with a more or less cloudy cornea. These cases must be carefully differentiated from those of buphthalmia, or infantile glaucoma, concerning which something will be said later. The main points of distinction are—first, that the intra-ocular tension is raised in buphthalmia, and, secondly, that the cornea in that disease is not only cloudy, but more strongly curved and larger than normal. Congenital opacities of the cornea may be total or partial, and the opacity may be complete or incomplete. The "sclerophthalmia" is applied to cases where there exists no sharp boundary line between the sclera and the cornea, which run almost imperceptibly into one another. The "arcus juvenilis" of Wilde is a condition closely resembling the arcus senilis, but of congenital origin. A good example of this condition has been described by Mr. R. W. Doyne and myself in the twenty-fourth volume of the *Transactions* of the Ophthalmological Society (1904). It should be added that many authorities still believe that corneal opacities are the result, not of intra-uterine inflammation, but of incomplete development. The fact that they tend to clear after birth does not tell strongly in either direction. Opacities due to injury at birth, so carefully described by Drs. Ernest Thomson and Leslie Buchanan, belong, of course, to quite a different category.

(a) A Clinical Lecture delivered July 19th, 1907, in the Post-Graduate Course of Ophthalmology in the University of Oxford.

Cryptophthalmia.—This exceedingly rare malformation, of which about a dozen cases only have been reported, is marked by the absence of eyelids, so that the integument stretches uninterruptedly from the forehead over the rudimentary eyeball to the cheek. Indications of the palpebral fissure may be wholly absent, or may manifest themselves by a horizontal furrow or by an anus-like opening. The eyebrows may be absent. The globe, which is always deformed, can be felt under its cutaneous investment as a rounded mass, varying in size from a pea to a cherry. The rudimentary eyeball, however, has reacted to light in some of the reported cases. Thus, in one of bilateral cryptophthalmia recently published by Goldzieher (*Centralbl. f. prak. Augenheilkunde*, Aug., 1903), twitching was noticed when a strong ray of light was allowed to fall on the bridge of skin which covered the eyes. The condition is generally bilateral. Associated ocular defects are the rule. Goldzieher (*loco citato*) believes that intra-uterine inflammation must lie at the root of the changes in the eyeball in cryptophthalmia, inasmuch as no arrest of development could account for the cicatricial tissue and adhesions that have been found in these cases. He supposes that when the conjunctival sac is forming, say, before the third month of fœtal life, an ulcerative process destroys the superficial tissues of the eyeball, whereby a considerable loss of substance ensues, which leads to adhesion between the raw surfaces and the skin covering them. In consequence of these adhesions, the formation of the conjunctival sac ceases. Inasmuch as the cornea has, so to speak, come to grief, the organs of the lid fail to develop, such as tarsus, glands, and cilia. Moreover, the embryological impetus to the separation of the adherent lids is wanting. This view, according to Goldzieher, fully explains not only the absence of lids, but also the undifferentiated condition of the skin-covering in cases of cryptophthalmia (for abstract of Goldzieher's important communication see *Ophthalmoscope*, Vol. II., 1904, p. 135). On the other hand, Van Duyse adopts the theory of amniotic adhesions to explain the production of cryptophthalmia. Lastly, defective development has been invoked by some authors as the cause of this rare malformation.

Buphthalmia, or Infantile Glaucoma.—The last but by no means the least important condition to be described is that curious and rare affection variously known as buphthalmia, hydrophthalmia, megalocornea, and infantile or congenital glaucoma. In a pronounced case the appearances are so characteristic that once seen they can never be forgotten. Thus, one—or more commonly, both—eyeballs are much larger than usual in babies, the corneæ are generally more or less opaque (milky-looking), and obviously globular, and the intra-ocular tension is notably raised. The anterior chamber is deep, the iris and the lens may be tremulous, and a glaucomatous excavation of the optic disc may be found if ophthalmoscopic examination be possible. A degree of photophobia is commonly present. The eyes, as a rule, are myopic. In all the early cases I have myself seen, more or less sight was present. But if the disease cannot be checked by treatment, it is apt to entail blindness. A few instances of spontaneous cure, however, may be found in the literature. The progressive enlargement of the eyeball may lead to the production of rents, resembling supplementary pupils, in the iris, as in one of my cases, to clefts in Descemet's membrane, as in another, to dislocation of the crystalline lens, and to intra-ocular hæmorrhages.

With regard to the etiology of buphthalmia, there exists considerable divergence of opinion. Everybody agrees that enlargement of the affected eyeball is the direct result of intra-ocular pressure acting upon parts which are as yet extensile and yielding. It is further admitted that the pathological feature of these cases is to be found in the existence of adhesions between the periphery of the iris and of the cornea, which impede the exit of fluid from the eye, and thereby lead to heightened intra-ocular pressure (Cross). The point at issue is with regard to the cause of these anterior synechiæ, for that is what they really are. In the year 1889 Horner expressed the view that they represented developmental anomalies. It is held by Mr. E. T. Collins (Norris and Oliver's *System of Diseases of the Eye*, 1897, Vol. I., p. 424) that they result from "a failure in the separation of the anterior fibro-vascular sheath from the back of the cornea." It is clear that such adhesions would prevent the passage of the intra-ocular fluids into the spaces of Fontana, and also that as the eyeball enlarged, the adhesions might yield, thus accounting for the cases of spontaneous cure of buphthalmia. On the other hand, as I have pointed out elsewhere (*British Journal of Children's Diseases*, 1905), most of the cases of buphthalmia that have come under my care have very obviously been the subjects of congenital syphilis. This observation has led me to suggest that the synechiæ, so far from being a developmental anomaly, are attributable to an intra-uterine irido-cyclitis of specific origin. As a point telling in favour of my view, I may say that I have on several occasions seen cases yield to prolonged treatment with mercury and chalk. The histological appearances of buphthalmic eyes are, to my mind, more characteristic of inflammation than of developmental defects. For example, the iris is fibrotic, and the ciliary body often shows evidences of former inflammation; the peripheral parts of the cornea, besides being attenuated, may be infiltrated with cells and permeated by fine vessels. These changes, I admit, might possibly be of secondary production, but I believe the evidence points rather in the direction of their being primary and the essential cause of infantile glaucoma. In my experience, the fact that buphthalmia is seldom associated with other anomalies, unless it be with plexiform neuroma, tells in the same direction. Reis (v. Graefe's *Archiv für Ophthalmologie*, LX., Heft i., 1905) and others have attached importance to the fact that in these cases the canal of Schlemm is more or less obstructed, if not actually absent, as a congenital defect. Obliteration of the venous channels, however, could come about as the result of anterior synechiæ, much as it is known to supervene in old cases of glaucoma in the adult (Parsons).

Microphthalmia and Anophthalmia.—The two conditions of microphthalmia—that is, an abnormally small eyeball—and anophthalmia—that is, an absence of the eyeball—have been placed in a separate category because of the divergence of opinion as to their causation among those most competent to express an opinion. There are some, as Hess, who adopt the developmental theory, and others, as Deutschmann, who voice the inflammatory theory. It is sometimes difficult or impossible to say where microphthalmia ends and anophthalmia begins. We shall do well, I think, to adopt the view enunciated by Messrs. Collins and Parsons (*Trans. Ophthalmological Society*, Vol. XXIII., 1903, p. 244), which is to the effect that no case should be classed as one of anophthalmia if on microscopical examination the least trace can be found in the orbit of retina, optic nerve, or, indeed, of any part of the nervous apparatus of the eye. All other cases, no matter how insignificant and functionally useless the eyeball may be, are examples of microphthalmia. It is a little unfortunate, from a practical point of view, that this scientific distinction between the two conditions can be established with certainty only by a more or less difficult microscopical investigation.

Of *anophthalmia,* as defined above, I have never seen a case. When the defect does occur, which must be very rarely, it seems always to be associated with grave developmental deficiencies in the central nervous system, such as absence of cranial nerves, of olfactory lobes, of optic chiasm or tract, or of the external geniculate body. On the other hand, *microphthalmia,* especially in its slighter forms, is tolerably common. A difficulty in diagnosis can arise only in pronounced cases. Under such circumstances the palpebral fissure is unusually short, and no trace of an eyeball is to be seen on superficial examination. At most, a globular body, of hard consistence, perhaps no bigger than a pea, is to be felt at the back of the orbit on deep palpation through the upper eyelid. Such an examination in the case of a young child is best made under the influence of a general anæsthetic. Even then, when the little finger is introduced into the conjunctival sac, it may be difficult to affirm the absence of a rudimentary eyeball, owing to the smallness of the palpebral aperture. In another and very interesting class of case, the apparent absence of eyeball is associated with a fluctuating cyst in the lower or (much more rarely) in the upper eyelid. Such cases are spoken of as "microphthalmia with orbital cyst." The cystic growth is then by far the most prominent feature of the case. It has been shown by Ewetzky, Lang, Collins, and others that the cyst, in the walls of which retinal elements can often be recognised with the microscope, communicates with a rudimentary eyeball at the back of the orbit by means of a tubular process, also lined with retinal elements. In explanation of this curious condition, it is supposed that the fœtal ocular cleft is closed by adventitious tissue, which eventually bulges out into a cyst, one effect of which is to retard seriously the proper development of the eyeball. Into other theories of causation, such as those which are associated with the names of Kundrat and Ginsberg respectively, we need not enter here.

CONCLUSION.

In conclusion, let me say that I am painfully aware of the shortcomings of this lecture, in which a few only of the congenital anomalies of the eye and its appendages have been described. Several other conditions of at least equal interest, such as albinism, cataract, and anomalies of the fundus oculi, have been omitted. For an account of these and of other anomalies I feel I cannot do better than to refer you to some of the larger text-books on the eye, among which I would signal out for special mention Fuchs' *Ophthalmology* and Parsons' *Pathology*. For anomalies of the fundus it is impossible to praise too highly Frost's *Ophthalmoscopic Atlas* (1896).

NOTE.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Robert Saundby, M.D.Edin., Hon. LL.D., Hon. M.Sc., F.R.C.P.Lond., Professor of Medicine in the University, and Senior Physician to the General Hospital, Birmingham. Subject: "The Sphygmomanometer in Medicine."***

THE PROFESSION OF MEDICINE—ITS FUTURE WORK AND WAGE. (a)

BY WILLIAM EWART, M.D., Cantab, F.R.C.P.

Senior Physician to St. George's Hospital, and to the Belgrave Hospital for Children.

THE PROFESSION AND ITS TWENTIETH CENTURY CRISIS.

I MAY put to you briefly as general propositions the views I have to express. Although the laity has much to discover in this constellation of ours, we are being a little better focussed and better understood. The sign of the profession is in the ascendant, and everything points to its gravitating into the orbit of the State. At the same time strange perturbations are noticeable within it, and to these I have to call your attention under the name of our twentieth century crisis.

Looking back, there is no profession of greater antiquity, yet none so truly young. The history of humanity is our history, and its future our future. Their joint record can be but beginning. Are we not still fighting for dear life against deadly foes? Ages ago it was the mammoth. Now the microbe only remains; but its days are numbered, and the era of health with its peaceful developments is in sight. The profession is only just cutting its back teeth, in the weirdness of puberty.

Had a man stepped forth in ancient Greece or Rome equal in wonders to the youngest of our qualified men he would have been accounted a demigod. We have thirty thousand such in the kingdom, and they pass unnoticed, as a negligible quantity. But a body controlling so much power cannot remain a cipher. We need only look back little more than a century, as the whole change has occurred in that time. Its wage, its status, and alas! its routine, have remained what they were. But a transformation has been silently accomplished within it. It held the shadow of knowledge; it now holds the substance. It had laboured long in hopeless efforts to be of use; it now waits upon humanity with the most brilliant service. Yet it ingloriously remains "Cinderella," the humble maid of all work.

The Profession—What is it? What ought it to be? What is it going to be?—The question has been asked before; but never with so much point or greater uncertainty. As the moulding of its future is to be partly within your own hands. you must bear in mind its attributes. The famous motto, *Liberty, Equality, Fraternity,* which has proved elsewhere not at all a good fit, would almost seem to have been borrowed from us, for we truly own those characteristics.

Fraternity ranks first: the telling title of "confrères" will identify us anywhere as members of *the* profession. It implies our essential independence and equality, and the absence of any hierarchy among us beyond that of elder brotherhood; and it also suggests the reciprocity without which the profession cannot subsist.

Freedom must ever remain our boast. But complete independence from the State is no longer for us a condition of existence as in darker ages. Independence was then vital to the progress of science. Our need is now no longer for the liberty but for the means of research.

Equality and its Duties.—Our equality is not a mere sentiment: it has its responsibilities. We are not so narrow-minded as to be intolerant of superiority, or anxious to level down the taller heads. We would rather be illogical, and put up with inequalities such as a Harvey, or a Laennec, or a Lister. But for the body of the profession we stand for equality:—Equality in education, equality in qualification, equality in status, and equality in wage. Only this carries with it serious obligations: henceforth but one set of standards, *the highest*. Our equality is that of an education which levels us all up, and of a qualification which confers upon us a high status; and there should never be any falling back in respect of outward dignity or of that within from that high level reached during our fellow studentship, which our life's labour should only further raise.

Altruism.—But there is another attribute, quite unique, which no one has ever been tempted to steal from us. Call it a fault or call it a virtue, we must agree to live with it because it is constitutional but very awkward to bear and delicate to touch upon; a thing to be proud of like an honourable scar, yet carefully concealed; and the disguise invented as a veil is that puzzle of the laity—"professional etiquette." We cannot quarrel with our altruism, which is our chief distinction. But as it is at the bottom of our crisis, and as we cannot subsist on hard work and a proud title, plain common sense must be brought to bear.

THE CRISIS IN ITS TWO ASPECTS—ECONOMICAL AND PROFESSIONAL.

We are in the throes of a double crisis: an

(a) An Inaugural Address delivered, at St. George's Hospital on October 1st, 1907.

economical crisis which affects a large majority of our numbers, and a *professional crisis* which threatens a previously compact profession in its corporate capacity. The situation itself and its great factors are entirely new. The earliest symptoms were overlooked and subsequently misunderstood. They were treated symptomatically without any reference to their cause; and the same symptomatic treatment runs risk of being repeated, as fresh symptoms continue to break out in connection with the individual and with the profession. As both crises have identical and reciprocating causes no separate remedy can exist for either, and any drastic measures would be dangerous if one-sided.

Before we can attempt to legislate for the future we must grasp the inevitably progressive nature of our changes. The chief cause of the economic crisis is our immensely growing success in reducing the prevalence of disease. That which mainly constitutes our professional crisis is the unlimited growth of specialism as the penalty of our progress: we have got in some way to fit it in, or we must fit in with it. The third, which takes effect in both directions, is the headlong change in the times, with which our old routine is quite out of touch. But we also have to take a clear view of the conditions as they now exist within the profession itself.

The Present State of the Profession.—What is the profession? And where is it? It is becoming increasingly difficult to be definite in speaking of the profession as a whole; and hardly any general remarks can apply with equal point all round. Yet, as the laity look upon us as a definite entity, we must shape the argument upon their concrete view, and use the word as a conventional formula for that which to us is really a huge abstraction. What are the facts?

"Pure medicine" and "pure surgery" are both dwindling by chronic cleavage. The great section of "pure surgery" rejoices in exceptional activity and in the absence of any grudge, whether from the body of the profession or the public. Moreover, thanks to the ever-increasing risks to life and limb from the harnessing of the forces of nature, it will continue to be in some request apart from the prevalence of disease. But "pure medicine" is left as severely alone as possible by both. In like manner most of the surgical sub-specialities are in work; but the medical preserves are shot over from every quarter without much regard for any genuine title to the ground. It thus happens that, though the long and gratuitous labour of research is mainly borne by the medical section, they are not as welcome as the quack to a meagre retribution for its fruits; whilst the surgeons are allowed by a public eager to be operated a fair acknowledgment for the time and skill they more largely devote to practice.

There remains the vast body of general practitioners, the bone and sinew of the profession, more homogeneous through the pervading similarity of their avocations, but more isolated by their exacting duties from professional intercourse even in towns. But within recent years a great and hopeful beginning has been made, thanks to the energy of a select few in their number, and to the devoted efforts of the officials representing the British Medical Association throughout the Empire, which should end eventually in the personal participation of all or of a large majority in the organisation which has been elaborated for them. Within that body the disparities are considerable, the great changes which have been gradually worked upon the profession having told unevenly in the direction of increased labour, technical, professional, and charitable, and of diminished emolument. But an adequate living wage is the exception; whilst the worst predicaments are too serious to be further endured.

This complex and strained machine of our profession needs expert handling to save it from being wrecked. None of our specialities, even the most scientific, can be taken as fair exponents of the requirements of the whole. On the other hand, even a complete combination of all general practitioners could hardly be expected to negotiate the affairs and fight the battles of a profession in which specialism is taking, in respect of remunerated practice, but particularly of study and of discovery, so considerable and increasing a part. Moreover, all groups alike have had practically to resign the technicalities of "research"—that latest and tallest of our branches which alone can give our full height when it comes to "sizing up" the profession.

Thus, whilst general practice offers the least of limitations, we look in vain for "the profession" as a concrete and complete working unit. Yet that unit is not altogether a myth. I had almost left out our better part, our students. In our fragmentation the great bond of union remains for us our joint study of man, and in this they are our living link. Perish the thought of any "specialisations" within their curriculum, which, when combined with an equally complete general education, alone now reflects the comprehensive nature of that study, and is the only stage at which there is any complete integration of the profession and of its objects, without difference or distinction between the workers.

The Professional Crisis.—The extensive field of specialism must continue to grow. Does this read practical dismemberment through divided interests, and the end of our influence as a great fighting unit? Is it with us "*Finis Poloniæ*"? That prospect is before us unless we can provide some timely cementation, for the safety of the profession and of specialism itself. Some of the risks of the latter are obvious enough. They have not hitherto included the struggle for existence, though this might easily eventuate in some of them.

The Economic Crisis.—The field of general practice has been for many years contracting, and is bound further to contract. The doctors are too many, the patients too few. In short, there are not enough cases "to go round." At the present accelerated rate of prevention there will soon be little left of preventible disease to attend. And no royalty can be raised on the independent employment of any device of such startling simplicity as the free use of water and boracic powder to fresh wounds to prevent inflammation, or "open air" in a tent with plenty of good food for the treatment of consumption, for that is the kind of *ridiculus mus* for which mountains of research had laboured so long without any compensation.

The altered conditions of life must tell upon local practice whether in town or country. Sentiment still pleads for the devoted family practitioner. But these days are "matter-of-fact": and no man can in the future regard the personal allegiance of those who consult him as a reliable source of income. Nevertheless, in the wealthy districts there must always remain in spite of all drawbacks a fair opening for local practitioners if only their number could be limited.

Less precarious perhaps is the practitioner's hold on the humbler class of practice, particularly under the provident system. But this has given rise to crying abuses under which he is still the sufferer.

Owing to the increasing size of our great towns entire districts are tenanted by a population little removed from destitution, in the service of which his ministrations, not less valuable, not less faithful, not less honourable than elsewhere, lead neither to honour nor to a compensation compatible with the dignity of the profession. That is our sorrow.

What is the upshot? Let me quote from the *British Medical Journal* for September 7th and 14th:—

"The average income of the British practitioner has been variously estimated at £200 to £250 a year. . . . The chances of being able to save even to the extent of the return of the capital expended in education are in a large proportion of cases slight; while reasonable provision for old age, after family expenses are met, is difficult and too often impossible." Is this the wage of lifelong self-sacrifice and of the highest skill?

The odium of so great a reproach has not been truly our own; but we should make it ours were we to fail to concentrate upon its cure the entire strength of our united body, and for that purpose alone, if for no other, we need a compact profession.

The Causes of the Crisis.

To dispel any doubt as to the permanent character of the changes it is enough to enumerate their causes.

The prime cause is the spread of that old tree of knowledge of good and evil. The immediate causes are its fruits, chiefly of 19th century growth. First on the side of the laity:—

1. The vulgarisation of facts and fallacies by our irresponsible Press.
2. The genuine growth of education, particularly in science.
3. The resulting *free thinking and liberty of conscience* in matters medical.
4. The independent individual inquiry for specialism on the one hand: and on the other—
5. The recrudescence of the innate fascination for *home treatment*—no longer with simples, but with compressed remedies.
6. *The emancipation of the patient* which sums up these tendencies.
7. The reversion to *Nomadism* or a wandering life—with all its good and all its evil—a taste fostered by the enormous growth of rapid locomotion.
8. Nomadic restlessness and instability, as it affects the conditions of practice.
9. *The decline of invalidism*, as a result of "open air" and of an active life.
10. The promotion of health by the remarkable spread of physical hygiene, particularly among women.
11. The salutary influence of the growing moderation in the use of alcohol.

Much of all this is the harvest which we have sown. Much more remains which can only be described as the direct handiwork of the profession:—

1. The increasing knowledge of the nature of disease; of its treatment; and of its prevention.
2. The suppression of many decimating infectious diseases.
3. The surgical cure of many intractable chronic ailments;
4. The inevitable specialisation of the study of disease;
5. The progressive growth of specialism in practice; and
6. The attractions exercised by the success of specialists, which tends to swell and overcrowd our ranks.

All these are new facts in the history of the world. Can we pretend to arrest their progressive development? If not, is it likely that the new situation can be met by anything short of a new departure on our part?

THE HARVARD "POLICY OF PERFECTION."

What is the forecast? Is our crisis the herald of recovery—and not the beginning of a natural death for want of anything more to cure? If any doubt should exist we need only look where coming events cast strong shadows before. Twelve months ago this school was represented at Boston by your delegate, at the inauguration of the new Harvard Medical College by the illustrious President, C. W. Eliot; a climax to similar achievements at New York, Baltimore, Chicago, and other great cities in the United States, as well as at the Universities of Toronto, Montreal, and Winnipeg in the Dominion of Canada. They all proclaim what the New World thinks of the prospects of medicine.

The new "Temple of Science"—for no other word could express its magnificence—stands as a sign of the times and a symbol of a principle with which the name of Harvard may deservedly be connected: "To science the highest place in medicine; to medicine the highest place in science."

The Harvard policy of *high standards*, not less consistently pursued for the preliminary than for the professional education, bears witness that medicine is still young, its advance only beginning, and its efficient function marked out among the institutions of the younger countries as of supreme concern to the community. This will be more clearly seen as we inquire into the public aspect of our calling and of our work.

THE STATE AND THE PROFESSION.

(A) THE VALUE OF THE PROFESSION IN THE STATE.

(1) *The Conservative Function.*—What is the profession in the State? Not, as the *Tiers Etat* claimed to be, "*Everything*"—the last of its conceivable errors would be Socialism—but much more than is commonly suspected. Above all conservative, and above all progressive, its antiquity and stability are not merely ornamental, but columns of support for our institutions. Its conservatism, copied from the teachings of Nature, spreads as a lesson which our time is least fitted to supply. Our own unhalting progress is equally safe from the spirit of reaction, and from that of revolution. Even under mob rule we could feel secure; for it is something to be so poor as not to invite spoliation; it is much more to be so skilled as to be indispensable. In reality we stand as the political body whose fabric shows least signs of "rocking," and of which can confidently be said in sight of impending changes, *impavidam ferient.*

(2) *The Function of Progress.*—No less precious than this staying function is our perpetual youth with its immense working power. When humanity shall have passed through its era of disease our function of progress will stand better revealed, in the promotion of its highest physical, intellectual and moral development. Potentially it is so now, to the knowledge of the better informed.

(3) *The Educational Function.*—Faust could not have lived within the last 150 years, or he would not have included medicine in his catalogue of barren studies.

Our students and their labours are a wealth in the State. Their arduous curriculum has often proved a stepping stone to distinction in other careers. Its wide and practical training is worth taking for its own sake, apart from any idea of practice; and it may be begun quite early without any fear of eventual waste of the labour bestowed in this direction. For the community the educational value of the profession will continue to rise with the growth of its higher specialities of research.

(4) *The Advisory Function.*—There are few questions relating to the welfare of the race, besides the social question itself, in which its deliberate opinion would not be the most important of all opinions to ascertain. There is none within its immediate competence greater than that of national education. Where else can be found the expert knowledge of cerebral physiology and pathology to adjust the increasing intellectual burden to the growth of the physical capabilities of the child? A service hitherto uninvited, which the profession will in the future be required to render to the State.

(5) *The Political Function.*—For the exercise of this function it has no longing. Intolerant only of error, it can never surrender its conscience to party, and must remain above the arena. But in any future political redistribution its integrity of purpose and disinterested benevolence may count; and duties will attach to the power which it owes to knowledge and to highly trained aptitudes. Its legislative fitness is displayed in the important growing sphere of medical politics. Lastly, the contingent of able and highly educated women which has of late years joined its ranks is an accession of consultative efficiency, as this completes its practical representation of the entire interests of humanity, man, woman, and child.

(B) THE VALUE CONTRIBUTED TO THE STATE.

(1) *Do ut des.*—In all ages the profession had contributed service for which it had earned various recognition, as priests of Hygieia at Cos, and as Greek slaves at Rome. But never before Jenner had it contributed actual value. The fact is startling, yet true, that whilst there is no profession but this handing to the State immense treasure year by year, if this be merely computed as wage earning value on the human life saved, all other professions have State subvention, establishment or endowment, to say nothing of other rewards that fall to their lot. Alone, the profession of medicine, the all-giving, is not assisted, not even with the education for the supply of that wealth.

In India, 5,000,000 of our fellow subjects have perished of the plague in the last seven years, in spite of the labour lavished by our profession upon the study of its treatment and prevention. The day will come when we shall succeed in abolishing forever that ghastly toll. What reward will this profession receive for the labour of its sons?

In the light of past experience shall we call it again "nothing," as in the other big transactions headed smallpox, typhus and cholera, diphtheria and phthisis, and tropical malaria? "Nothing," not even the out-of-pocket expenses for the means of research. The profession labours and gives; the State takes—where is the "*do ut des*"?

Again, the incalculable value of the disablement from work now largely saved by preventive hygiene is an unacknowledged gift, not of any surplus of wealth, but of the actual means of livelihood of the giver.

But this is not all. Preventive pathology is becoming a definite speciality; and the profession will consist soon of two uneven sections, that of "practice" and that of "research." The latter works for the gain of the State and against that of the profession. To suggest that its support should be charged to the profession would be neither common sense nor common justice. As a branch of national defence it contributes immense value, and has a higher claim to national subvention than the King's forces, which contribute nothing and cost so much. All this makes up a heavy debt, with but meagre instalments on the other side of the account.

(2) *The Nation's Vicarious Charity.*—Not less gigantic is the contribution received by the State from the great branch of practice, in the shape of unrequited or ill-requited service to the community. The "Nation's almoners" is the only title which could express the mission of many of our number in the poorer districts. If anything could be more pathetic than the rags of the apothecary in Romeo and Juliet it is that quiet devotion of the surgeon of twentieth century attainments, as he toils under his heavy burden either totally unpaid, or at a wage not presentable. Innocent of causing the poverty which he attends, a heavy toll of overwork with underpay is systematically levied upon him, which, strange to say, does not relieve him of the poor-tax or of calls for the support of many charities.

Our profession never did admit, and the State never dare admit, that there should be any distinction between the treatment of the poor and the treatment of the rich. Justice then would claim not less but better pay for the appalling labour of ministering to the poor. It was Locock, so says tradition, who replied to the august visitor who summoned him to the bedside of the great Queen, "Her Majesty shall be treated as well as the most humble of her subjects." That great lesson has passed unheeded. The humblest have continued to be treated as queens, but for what honorarium! From the purely moral standpoint of "virtue its own reward" a double wage might be said to have been won, as humility and self-humiliation have been as conspicuous as charity. But these are virtues for individuals to practise apart from their profession. Upon the profession itself their exercise is deleterious and demoralising.

The State which ignores sentiment or pure charity as motives has to answer for the health of the masses; it cannot escape from that law. As regards the pauper class, the liability has been acknowledged; and for that section of its health insurance the public pays the whole because the pauper can pay nothing; but for the vaster insurance of millions who can afford only totally inadequate compensation it pays nothing at all. An immense burden belonging to the State is shifted on to the shoulders of its hard-ground almoners. But no record is kept of the transfer, nor any voucher given to show that business has been transacted for the State.

For the unofficial press the whole transaction goes under the simple heading, "Charity and Charitable Work." From society more of contempt is earned than of pity by the toiler of the slums. It is not perceived that charity is being done for the Nation—*vicarious charity*—and therefore done unto the Nation itself.

(c) The Duty of the State.

Sanitas Sanitatum et Omnia Sanitas.

The profession have hardly realised, much less the laity, that, with the acknowledgment by statesmen that the health of the people is the primary care of the State, a turning point was reached. That principle places the profession in an entirely different position, as on examination a great deal of its work is work done for the State; and it is inevitable that the profession should become more and more its servant. As the organisation of the public health service has brought the new principle into operation, the system cannot remain limited, but must ultimately reach its normal development. This involves definite consequences—under the general headings of the duties of the State, and of the rights of the profession. The functions of the latter, its status, and its pay must tend to be regarded more and more as matters of public utility.

It is manifest then that the quality of our professional work is not a matter of indifference to the State which absorbs it so freely. Good work is said never to be wasted—a comforting view, as the less our labours have profited us, the more certainly must they have been of some use elsewhere—but, as it is bad economy to spoil the quality of good work by breaking the spirit of the worker, our legitimate requirements are not foreign to public utility. They will be appreciably furthered by the fulfilment of the duties to which the State is pledged by its own policy:—(1) The organisation of the prevention of disease and of the cultivation of health; and (2) the organisation of research for both those objects. The nature of the measures required is not open to question: a State examination to ensure the highest efficiency; and a ministry of public health to undertake vast responsibilities too long officially ignored.

Our Remedies and Practical Ideals.

Quality versus Quantity.—Relief cannot be obtained from any source immediately, but would come with least delay and with coupled honour and efficiency from *restricting our numbers* by adding to the labour of our apprenticeship, and to the quality of our work. These are not features of trade unionism—a policy with which we have little in common. They are principles of duty and of progress, and practical applications of the rules of political economy, for the profit of the employer as well as the employed.

The problem of the attendance on the poorer classes and of its proper remuneration is difficult. But why should it be insolvable, with the co-operation of our employers and of the State? In this matter the word *impossible* should have no application, for of all unpractical suggestions, the worst were to submit to a continuance of the present plight of a noble profession.

Our Future Work and Wage.

I believe that in fairy tales the fairy rarely gets any thanks. For the fairy "Medicine" the chief thanks has been the request for further wonders—a business-like view of our *raison d'être*, and of the value as an insurance of any support given to the profession, which only calls for the comment that the increased labours in prevention which are demanded must further victimise us. President Eliot eloquently urges all medical schools "to supply the twentieth century physician who shall prevent the access of epidemics, limit them when they arrive, defend society against bad food and drink, and reduce to their lowest term the manifold evils which result from the congestion of population." But these utilitarian claims will extend far beyond the safeguards against mortal disease and economic losses incidental to sickness. There are other needs, less familiar to lay thinkers, and consciously reasoned out only by a minority of the profession, but voiced by the logic of facts. In addition to "the teaching" and "the study" of prevention, guidance will be needed in wider fields for the cultivation of health. The State looks to us for the supply of a vigorous as well as sound race of workers and warriors. But there remains another great department, that of the mind. We are still struggling with the elementary stage of the cure of mental disease; and the study of its prevention is hardly begun. But the cultivation of mental health, with all its physical, intellectual, moral, social and political consequences, is a vast duty for our future occupation. Who else can undertake it?

The unhallowed perpetuation of sinister heredities, and other elementary failures in eugenics, call for a remedy. Wider still is the task of strengthening mental and moral health in the growing generation by a judicious interaction of the physical and of the mental factors; and of encouraging among adults that physiological rectitude without which there can be neither longevity for the individual nor increase for the race. In all these directions there is ample scope for the study, the teaching, and the individual service of the profession, but for the success of its ministrations it will need the support of the State.

The future earning power of the profession is not easy to estimate, but we may infer that as emoluments for private services decrease, there will be a slight tendency towards an increase in remunerated public work.

We have seen our busiest days in the treatment of Disease, henceforth our livelihood must be increasingly derived from the Care and Culture of Health. The greater part of that remuneration must ultimately be derived from the State. The long delayed medical inspection at schools is a first instalment in that direction; but much larger work should follow, which would employ larger numbers. The registration of each individual health, with a view to prevention, is not a Utopian view, but a measure suggested by common sense. Each growing leaf in tobacco plantations is registered and watched. Our own Excise appoints a special officer to watch the still. We shall not succeed in stamping out tuberculosis until a health watch is kept over each life, that by timely treatment it may be made germ proof. The highest skill is essential for this class of work, and will call for adequate remuneration. Personal certificates of health could be paid for by the smallest number of taxpayers. For the majority, any difference unpaid by the individual would be charged to the public funds. What applies to certificates would *a fortiori* apply to the attendance on actual disease, which could no longer be charged as a private tax on the practitioner.

CONCLUSIONS.

This imperfect sketch can only suggest outlines, not any of the details:—

(1) As a profession we can advise and we can act: but the business of health is of the State. *State organisation and subvention* for increasing labours undertaken in its service are unavoidable, even at the cost of public treasure, and for us of a nominal loss of independence.

(2) *A ministry of public health and a State examination* are the definite steps for immediate contemplation.

(3) Our practical policy is to be "prepared for any fate" by an *unlimited adaptability* for the coming changes, of which we only know that they will exceed the record of the past. And this means raising the preliminary educational standard to its highest pitch, which can never be too high for the possibilities ahead. This is also our only plank of safety from the dangers of over-crowding and of disorganisation.

(4) Indispensable to teachers and to rulers, our co-operation should be worthy to command its own terms.

(5) The fundamental reform in the status and remuneration of the profession demanded by its vast labours and service can only be won by high standards of self-improvement, and by the combined efforts of the highest and most influential with the rank and file.

(6) The details of reorganisation are beyond the wit of individual man, but would evolve from the operation of the four principles which are essential:—(1) Exclusion from our portals of any but the highest preliminary educations; (2) uniformity of the professional State qualification; (3) recognition of the equality in claim to adequate remuneration; and (4) assumption by the State of those responsibilities which are not ours but of the State.

Our future wage should not fall sort of that competency which allows scope for the best work. Wealth it never will be. As of old it must remain largely a consciousness of doing our best as healers and helpers, as students and teachers, and as a moral and intellectual *élite*; with the added satisfaction of belonging to a profession not only honourable but honoured.

DR. PETER FRASER, medical officer of health for the Carnarvonshire Joint Sanitary Authority, is surrendering his post in order to take up the position of a medical missionary in India.

THE GOVERNMENT'S SCHEME TO PROMOTE THE UNQUALIFIED PRACTICE OF MEDICINE.

By J. C. McWALTER, M.A., D.P.H., M.D.Brux., F.F.P. and S.Glas.

Of the King's Inn, Barrister-at-Law.

LET us clear our minds from cant. What is the genesis of this Notification of Births Bill? and what must be its effects—on the population and on the practitioner?

To start with, we must remember that it is not merely futile to discuss the matter even now, for, although the Bill has passed, the Act is an adoptive one, and if strong objection can be shown to its effects, it simply will not meet with any large measure of acceptance by local authorities.

Huddersfield is a very progressive town, with a population under 100,000. It was blessed with a most intelligent and philanthropic mayor, Mr. Broadbent, and a most active and forceful Medical Officer of Health, Dr. Moore. They devised a plan whereby prizes were offered to mothers who kept their offspring alive to a certain age, and who notified the authorities immediately of the occurrence of a birth. On this notification nurses were sent to instruct the mothers in the care of the infants, &c. Apparently, as a result of these efforts, the infantile death-rate in Huddersfield went down greatly—although in 1906 it seems to have been only about 7 per cent. below the average, and Mayor Broadbent and Dr. Moore naturally rejoiced, and proclaimed in every congress and from every hill-top their success. So thoroughly did they succeed in influencing the public mind to believe that they had discovered an important weapon in dealing with infant mortality, that a Bill has been brought in and passed by the Government requiring doctors, under pain of a penalty, to give early notification of births.

I happen to have got myself into considerable trouble by questioning the wisdom of the Huddersfield scheme, but I am still unconverted, and do not think it wise that ill-digested legislation, based, practically, on a few ill-considered instances, should be thrust on the whole country. I contend that the effect of the Notification of Births Bill is to open wide the door for the unqualified practice of an important department of medicine by midwives or by persons of still less skill.

If Huddersfield is to be set before us as the Great Example of municipal righteousness in the production of a healthy population, and if laws, based on its example, are to be thrust down our throats, it cannot complain if we examine its claims to excellence more closely.

Obviously, it is idle to consider the death-rate of a small section of the population. You must look on the whole to gain any idea of the facts. The last statistics of Huddersfield show, I believe, a birth-rate of 22, and a death-rate of 19. It is a fundamental principle of vital statistics that an infantile death-rate is only an indication of importance as to the health of a locality when it is compared with the infantile birth-rate. Now, 19 is rather a small death-rate; it seems to compare very favourably with Dublin, where it is 25. But the Dublin birth-rate is 33, and hence the population of Dublin continues to increase two and a half times as quickly as that of Huddersfield. That is, under Dublin conditions—such as they are—the number of persons who survive to the service of the State is two and a half times as great as in Huddersfield.

These questions can only be studied profitably when we examine millions of examples. We have them in France. Practically every point of importance in the Huddersfield system is copied from French methods—but the population of France was forty millions thirty years ago, and is practically the same to-day.

I submit, therefore, that Huddersfield is a very bad, in fact, a fatal, model by which to regulate the families of the nation. Of course, I know that Mayor Broadbent and Dr. Moore would both insist that they were only anxious to check an apparent wastage in infant life, and had not the slightest desire to see the number of births checked. But I would point out, whilst giving them ample credit and praise for their endeavours, that we are bound to examine the facts as they work out—with all their attendant circumstances. If, therefore, we find that the difference between the actual birth-rate and total death-rate in Huddersfield is so small that it would mean ruin to the nation if the same figures prevailed in every other town, I submit that Huddersfield is not an example to be followed, or to be made the groundwork for general legislation.

I am open to conviction and correction on this point, but I believe that in every place—or certainly in the vast majority of places—where there is a low infantile death-rate, there is also a low infantile birth-rate. The question for us, as scientific men, to decide is, whether it is *post hoc* or *propter hoc*. The question is not only of the greatest importance to the British Empire, but also to the whole white race. If all white peoples continued to increase in numbers only at the Huddersfield rate, in thirty years' time the Japanese, with their high birth-rate, would overrun the world. Moreover, it is abundantly proved that where the infantile death-rate is kept small, a vastly larger proportion die in the third, fourth, fifth, and sixth years of life, and a vastly larger proportion of the survivors are afflicted with some bodily or mental defect and become burdens to society.

But what is the early notification of births for? It is to send an unqualified person to occupy the place of the doctor in superintending the care of the mother and child. She directs all that pertains to the hygiene of the child—its food, clothing, air-space, time of outing, and every detail of its life. Now, the sanitary inspector charged with these duties—this illegal medical practice—may, in a sense, never have seen a child before; she need never have been in a hospital, or seen a case of contagious disease; she simply holds the certificate of a sanitary inspector. Nothing is more certain than that the major part of her work will be to diagnose infantile ailments, and to prescribe for measles, scarlet fever, gastric or bronchial troubles, meningitis, &c. Of course, she will be ordered to do no such thing by the sanitary authorities, but from the nature of her avocations she will be consulted constantly about these things. The effect, therefore, of the Notification of Births Act, where adopted, will be to create a trade of unqualified practitioners. I happened to glance at the proceedings of the General Medical Council for 1898, and I find a practitioner, of unblemished reputation, haled before the Council to answer a charge—of what?—that, having a case of confinement under his care, he sent a woman to attend it during the interval between two visits! And we, at the public charge, propose to send out ignorant women to attend mothers and their babes, and to give instruction as to their care, where no doctor may see the child first or last.

The essential object, then, of the Notification of Births Act, is to send an unqualified person to direct the care of an infant, and at the public cost; though if a practitioner should do the same thing with his private patients, and with the most skilful nurse under his own observation, he would be struck off the register for it.

A WORD FOR TRYPSIN.

By A. K. MATTHEWS, M.R.C.S., L.R.C.P.

The utter powerlessness of medicine or surgery to relieve patients is frequently experienced by medical men, but never more poignantly than in the last stages of cancer. One therefore welcomes any success in this almost hopeless warfare, and it is with much pleasure I quote my experience of trypsin in a case of inoperable cancer of the tongue.

Briefly, the notes of the case are the following:—T.H., a boatman, æt. 58, no family history of cancer, no history of syphilis, and urine normal. When I first saw him he was suffering from large fungoid ulceration of the left side of the tongue, which had been slowly extending for seven or eight months. The tongue on the side of the growth was fixed, causing difficulty in speech and deglutition, and he was unable to take solid food. The salivation was excessive, and the hæmorrhage on three occasions severe, the loss each time being three or four pints. The submaxillary and cervical glands were greatly enlarged, causing stiff neck, and the pain in the growth and the glands was at times very severe.

There can be no doubt about the diagnosis, as he had been sent to Guy's Hospital, where he was advised that the case was too far gone for operation. Considering the extent of the disease, it was almost without hope that I recommended the trypsin treatment, and before commencing the injections I told T.H. they might give him considerable pain and not much benefit. He, however, welcomed any chance of relief, and I began the hypodermic injections of inj. tryp. co. (Allen and Hanbury), and liq. tryp. co. by the mouth.

Without exaggeration, I can describe the result as marvellous. After three daily injections (15 min.) he expressed himself as feeling "twice the man," his tongue was freer, and I could understand all he said. After a week's daily injections I increased the dose to 30 min., using it every other day with liq. tryp. co. t.d.s. He continued to improve rapidly. The glands entirely disappeared, the growth was reduced to half its size, no further pain, salivation greatly reduced, no recurrence of hæmorrhage, and speech and deglutition markedly improved. The effect constitutionally may be summed up in the man's own words: "I feel a different man altogether," and he began to look forward hopefully to tackle his work again.

I continued the treatment for a little over two months, always injecting the left buttock or flank. He experienced no pain, nor was there ever any sign of inflammation—in fact, nothing but the best results.

I left the case in the hands of another medical man (I was at the time doing *locum* whilst the practice was passing from one medical man to another), and I regret that my successor "had no faith in trypsin." The treatment was discontinued, and the man died six months afterwards.

Dr. H. writes to me that he saw no indication to continue trypsin, as there was "no pain or hæmorrhage," and death was due to exhaustion. Dr. H., however, includes a very important statement in his letter, in which he says: "I have now a case of pyloric cancer, and am going to give trypsin a good trial." *Verb. sap.*

The first meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine will be held on October 10th at 7.45 p.m. Professor W. E. Dixon and Dr. F. E. Taylor will read a paper on "The Physiological Action of the Placenta."

THE OUT-PATIENTS' ROOM.

CHILDREN'S HOSPITAL, PADDINGTON GREEN.

Habitual Dislocation of the Thumb.

By Arthur Edmunds, M.S., F.R.C.S.

Among the patients was a boy, æt. six, who had fallen down when a year and eight months old, and dislocated the terminal phalanx of the right thumb. Ever since the accident the thumb had been continually liable to a repetition of the dislocation, although at the time it was reduced in the usual way and efficient suitable after-treatment adopted. On examination one found that the terminal phalanx was acutely flexed upon the next bone with a marked rotation, so that its palmar surface looked almost directly backwards. There was very considerable impairment of the usefulness of the hand as the thumb was kept flexed into the palm. The dislocation could be reduced quite readily, and indeed the boy was able to do this for himself, but after reduction the slightest attempt at flexion of the joint reproduced the deformity. A skiagram was taken which showed that the end of the proximal phalanx was smaller and more pointed than normal, and it seemed reasonable to assume that this was the cause of the recurring deformity. In view of the extreme disability it was necessary to perform some operation which would render the joint more stable, or at least so stiffen the junction between the two bones that the thumb could be used. Habitual dislocations are by no means uncommon, and they are usually due to disproportion in the articulating surfaces of the bones which form the joint; as a secondary result of this, the ligaments which form the joint's capsule are often extremely lax. The strength of a joint depends upon two factors, in the hip joint, for example, the articulating surfaces are extensive and accurately fitting, so that dislocation is prevented even if the capsule were a little lax, in other cases, for example, the knee joint, although the articular surfaces are not very accurately opposed to each other, yet the ligaments and muscular structures which surround the joint combine to form one of the firmest articulations in the body. In the present case the deformity was, as Mr. Edmunds pointed out, due to the deformed condition of the proximal phalanx, which was pulled out of position by the tendons of the long flexor which are inserted into the base of the terminal phalanx. In order to rectify the condition it was obvious that the pointed end of the proximal phalanx must be removed with a liberal amount of the shaft of the bone so as to give an increased surface to articulate with the terminal phalanx. Fortunately so far as muscular insertions are concerned this piece of bone is unimportant, and the bone increases in length almost entirely from the other end. An incision of about an inch was made along the inner border of the thumb, the structures around the head of the bone separated from it until the last half inch was satisfactorily exposed, this was then removed with cutting forceps, and the wound sutured and dressed. As regards the ultimate success of the operation, Mr. Edmunds remarked, it is, of course, impossible to say, but there was no tendency for the terminal phalanx to fall into its previous faulty position, and there was no tendency to flexion of the thumb into the palm of the hand, so that it is probable that after the stiffness which is fairly certain to follow has worn off an excellent result will be ultimately obtained.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Pirogoff's Amputation.—Mr. Willmott Evans operated on a man, æt. about 60, who had been admitted for gangrene of the foot. About a month before, after a slight injury, several of the toes had become black with complete loss of sensation. After a longer or shorter time the toes had sloughed away, leaving exposed the four outer metatarsal bones, while of the great toe a portion of the proximal phalanx still remained. No extension of gangrene occurred, though the patient was kept under observation for several days. His general health seemed good; the arteries were not much hardened. Pulsation could be felt in the popliteal and slightly in the anterior tibial at the bend of the ankle. Some slight pulsation was palpable in the posterior tibial behind the internal malleolus. It was decided to remove the foot. The exposed bones were carefully covered with a dressing so as to lessen the chances of infecting the operation wound. The skin around the ankle having been cleansed, Mr. Evans entered a Syme's amputation knife at the tip of the external malleolus and carried it downwards and forwards at an angle of about 60° to the sole of the foot; it was then carried straight across the sole and then upwards and backwards to a point on the inner side about three-quarters of an inch below and behind the tip of the internal malleolus; this incision was deepened down to the bone. A straight cut was then made across the front of the ankle joining the extremities of the original incision. This was deepened, all structures being cut through until, the anterior ligament of the ankle being divided, the joint was opened. During this incision the anterior tibial vessels were divided, they were seized with Spencer Wells' forceps, though they bled but slightly. The bleeding also from the plantar incision was but slight and easily controlled. With the point of the knife the lateral ligaments of the ankle joint were divided. The foot was fully extended, and the posterior ligament was cut through and the tendo Achillis exposed. A saw was then introduced behind the astragalus and the os calcis was sawn downwards and forwards in the plane of the original incision and the foot removed. The skin and structures around the malleoli were carefully turned upwards for about an inch and a half; the tibia and fibula were then sawn from before backwards and slightly upwards, the plane of section forming an angle of about twenty degrees with the horizontal, the whole of the articular surface of the joint being removed. All discoverable blood vessels were tied whether bleeding or not, and the remains of the os calcis with the heel flap turned up so as to meet the sawn surfaces of the tibia and fibula. A silk stitch was then introduced uniting the periosteum of the tibia to the periosteum of the calcaneum. Skin sutures were put in, no drainage being employed. A light dressing of sterilised gauze was put on and very loosely bandaged. The patient was put back to bed with the leg lying on a pillow and gently held in place by sandbags, no splint being employed. Mr. Evans said this case was one of senile gangrene, and even at the present time there is considerable divergence of opinion as to the best treatment to be followed; in his own opinion the treatment may have to vary very much according to the individual case. The chief difference in treatment is as to the site of amputation; some surgeons are in favour of amputation limited to the affected part, while others urge that if amputation be done low down in these cases recurrence of gangrene is almost certain because of the thrombosed condition of the anterior and posterior tibial arteries. Therefore, they advise an amputation high up, say, the lower third of the thigh, as much more likely to be followed by recovery. There is certainly in these cases, Mr. Evans pointed out, a very great tendency to recurrence of gangrene after amputation, but the thrombosis of the vessels is not the only factor in the production of this gangrene; sepsis is almost equally important, and if sepsis can be avoided the risk of the recurrence of gangrene is much diminished. The chief points in determining the site of amputation to be adopted in senile gangrene are, he considered, the following:—

(1) The state of the vessels: if all the arteries supplying the foot are completely thrombosed the chance of a satisfactory result of an amputation low down is small, but if even one of the tibial arteries can be felt pulsating that in itself is in favour of the lower operation; (2) the character of the progress of the gangrene: if it stops completely and shows no tendency to reappear higher up, the less the risk of the lower operation, but if it is spreading, however slowly, there is always a large element of risk in any amputation low down. In this patient there was no evidence of any immediate extension of the gangrene, and there was definite pulsation in, at least, one of the tibial arteries; therefore he thought it justifiable to limit himself to amputation of the foot. When that decision was arrived at the question arose as to what amputation should be done: from the extent of the tissues already destroyed it was obvious that only two alternatives were possible: Syme's amputation or Pirogoff's. In deciding between these two operations we had, he said, to take into account the reason of the amputation, the condition of the patient, and the nature of the stump produced. For cases of disease of the bones of the foot such as tuberculosis there could be no doubt that Syme's operation was preferable, but when the cause is traumatic or strictly limited to the anterior part of the foot Pirogoff's method is the better. As to the condition of the patient the heel flap in the Pirogoff is much less likely to slough than the heel flap in the Syme, for the latter flap cannot but be more damaged in being formed. In a case like the present where the vitality of the heel flap was gravely compromised by the condition of the arteries the small amount of disturbance of the tissues in the Pirogoff operation was a decided gain. The value of the stump produced depended, in his opinion, greatly on the manner in which the operation was performed; when, as in Pirogoff's original operation, the os calcis is sawn vertically and the tibia and fibula are sawn horizontally, the treading part of the stump is formed by the soft skin just behind the ankle since the heel flap has to be rotated through 90°; such a stump is not well adapted for walking; this objection can be entirely done away with if the os calcis is sawn downwards and forwards and the leg bones backwards and upwards, for the rotation required of the heel flap is then only about 20° or 30°. A well-made Pirogoff stump is admirably adapted for bearing pressure, and he had known of a case of a double Pirogoff in which the patient could run freely on his bare stumps. It would have been noticed, he pointed out, that no tourniquet was employed. This was done intentionally, for he felt sure that a tourniquet favoured thrombosis and so prejudiced the vitality of the stump; and in these cases no tourniquet was needed, for the hæmorrhage was always easily controlled It had been seen in this case how very little blood was lost. Another point of importance was, he considered, the advisability of bandaging the stump as lightly as possible; just sufficient dressing was employed and a few turns of a bandage to hold it in position. It was hardly necessary to point out the intense importance of asepsis in dealing with tissues whose vitality was already greatly lowered. One other matter he might mention; it is always advisable to stitch the piece of os calcis to the tibia, either with silk or wire. In the present case he was content to stitch the periosteum as less likely to do harm.

The further progress of the case was satisfactory. Except for a little moisture at one portion of the skin wound the healing was by first intention; the skin stitches were removed at the end of a week; the wound was soundly healed in three weeks from the date of operation.

Paris, Sept. 29th, 1907.

Drainage in Gynæcology.

The history of drainage of the abdominal cavity does not go beyond 1850, says Prof. Pozzi.

Peasley, in 1855, was the first to have recourse to drainage of the abdominal cavity in every case where he feared the exudation of a liquid (pus, blood, etc.) into the abdomen, by placing in the vagina an elastic catheter, which penetrated in to the cul de sac of Douglas.

In 1867 Kœberlé recommended the drainage of the abdomen directly through the wound by means of a glass perforated wound; this practice was adopted with slight modifications by Spencer Wells, Keilt, etc.

Later, in 1872, the eminent gynæcologist, Sims, proposed draining systematically all cases of laparotomy, on the grounds that the death of every patient after the operation of laparotomy was due to septicæmia and that exudation was found in the abdomen at the autopsy.

The ideas of Sims were adopted by Nussbaum (1874) and Olshausen (1876).

In order to have a correct idea of the utility of drainage, it is necessary to understand the function of the peritoneum, in normal and pathological conditions.

In the healthy state, the peritoneum absorbs easily liquids of slight density (water, semen, blood).

Wagner demonstrated in 1876 that the serous membrane could absorb from two to six quarts of salt liquid in the twenty-four hours, and that a relatively large quantity of infectious substances could be eliminated by the peritoneum or encapsulated by means of exudations, without danger to the patient. But for this the membrane must be intact.

In every case, on the other hand, where the peritoneum is infiltrated and poisoned, its physiological properties are destroyed. It ceases consequently to be absorbent when it is macerated by ascites coexisting with a tumour, its epithelium being thus destroyed.

Drainage is indicated when there is positive or imminent infection of the seat of operation, and to ensure the evacuation of the liquids, and above all to avoid possible accumulation of blood.

In operations for salpingitis, some of the pus might fall into the seat of operation. If it were aseptic no harm would be done, but generally the wound is infected. By closing completely the incision, the microbes contained in the pus would produce peritonitis. If, on the contrary, drainage was practised, the infection is limited and the liquids secreted by the peritoneum against the microbes are evacuated at the same time as the microbes.

Drainage allows also sequestration of the infected spot, for around the drain plastic peritonitis develops; an artificial membranous canal is formed, protecting the neighbouring parts.

Each time, in laparotomy, the presence of a liquid, ascites or other, drainage must be practised and continued three or four days.

When an effusion of blood is produced, the drain should be used not only to evacuate the clots which would be absorbed with difficulty but also to produce hæmostasis, for, when capillary hæmorrhage meets with the rough surface of a drain or plug, it coagulates and the drain becomes thus an hæmostatic centre.

In great oozing of blood as in the decortication of a large tumour a drainage practised according to the method of Mikulicz becomes an agent of compression.

The drainage can also be done per vaginam, and many foreign surgeons give it the preference. In France, Richelot believes vaginal drainage superior to abdominal drainage.

M. Pozzi drains through the vagina only when it is completely opened at the end, that is to say, after vaginal hysterectomy.

Hegard drained by means of an enormous indiarubber tube, fenestrated, into which he introduced antiseptic plugs which were changed when they were completely infiltrated.

At present, in France, drainage is done by elastic tubes (tube of Chassaignac), supple but resisting, they are always fenestrated.

Another method, abandoned for a long time, after enjoying great favour, consists in the use of plugs.

It was Kehrer, in 1882, who brought this method back to public favour. Bands of aseptic or antiseptic gauze replaced the cotton hitherto in use. These plugs act like a drain; but thanks to their capillarity, they aspire all liquids and are consequently superior to the indiarubber tube, at least in the first few days following the operation.

In 1884 Mikulicz published an important pamphlet in which he recommended the method employed to-day by a large number of surgeons.

His method is not only a drainage of the abdomen, but also a plugging of a portion of the abdominal cavity.

Where there is a large denuded surface to be drained, two, three, or four plugs have to be placed together. When at the end of a certain time it becomes necessary to remove these plugs they are all stuck together, and to the edges of the wound; to withdraw them, a considerable effort is necessary and suffering is caused to the patient.

Mikulicz conceived the idea of placing these plugs in a bag. The bag, empty, is placed in the centre of the incision and pushed gently to the bottom of the wound. To this bag is fixed a long and strong silk cord of which the end is fastened outside on the wall of the abdomen by an adhesive plaster; the bag is filled with the plugs and then closed. At the end of a few days the plugs are withdrawn quite easily, one after the other, and finally the bag is removed by drawing on the silk thread, without causing the slightest suffering to the patient.

CORYZA IN INFANTS.

Coryza in infants is, as all know, a very troublesome affection, preventing the development of the child. Two or three drops of glycerine three or four times a day bring about a speedy cure.

MUSHROOM POISONING.

A few tablespoonsful of powdered charcoal or animal black in milk or water are sufficient to arrest the most acute symptoms.

GERMANY.

Berlin, Sept. 29th, 1907.

AT the Medizinische Gesellschaft Hr. Goldscheider communicated a note on

PERCUSSION OF THE LUNGS.

He first described the method in general use, and drew attention to the methods of Ziemssen, Gerhardt, and Krönig, and observed that they were capable of improvement, as they were not based on exact pathological knowledge of the anatomical relations of the apex of the lungs. These relations the speaker showed by drawings, and came to the conclusion that the apex was best percussed between the two heads of the sterno-cleido-mastoid. In percussing the apex of the lung from the back he did not percuss over the supraspinous fossa, as there was no lung tissue there, but recommended percussion over the two first ribs after the attitude proper for the examination had been assumed (sitting with the arms slung round a chair back). By this the shoulders were drawn widely apart on both sides, and the ribs exposed. Percussion performed in this way was of more value than auscultation. It should be performed lightly.

Herr Ewald did not think much of the importance of percussion based on anatomical position; it was a matter of the projection of the sounds of the lung into the neck, rather than of determining changes. The previous speaker had not mentioned a good kind of physical examination of the apices of the lungs, namely, direct clavicular percussion. He was in the habit of using a method that seemed useful to him, namely, percussion of the apex from behind.

Hr. Westenhoeffer observed that, with percussion between the heads of the sterno-cleido-mastoid, glands in that position might easily be percussed that might be enlarged in incipient tuberculosis.

At the Verein für innere Medizin Hr. Westenhoeffer demonstrated the organs from a case of

PLETHORA VERA.

A telegraph worker was admitted into the Moabit Hospital with symptoms of meningitis, and died in ten days. In the fluid obtained by lumbar puncture, and which flowed out under great pressure, leucocytes were found, and on puncture a second time lymphocytes. The autopsy revealed as the direct cause of death meningeal hæmorrhage into the left lateral ventricle; but besides this quite peculiar features were observed. All the organs were overfilled with blood (heart, liver spleen, kidneys, stomach, pancreas, and bones). The organs preserved in formol still showed a dark blue-red colouration. The case was one of plethora vera. The etiology of the affection was completely dark. The watery constituent of the blood-serum was not diminished, as shown by Weintraub, but somewhat increased; there was no thickening of the blood therefore. The disease in the bone marrow was characteristic; this was dark red, and it looked just as it did in little children, in a state of infantilism. The patient did not suffer from cyanosis, but the face was very red. He had never had any signs of circulatory disturbance, and had been of a quiet temperament. The spleen was not greatly enlarged, and its tissue showed no changes. The blood did not differ from the normal, and in particular it contained no nucleated red blood corpuscles. The heart was not enlarged, and showed no deviations from the normal. It was the same with the aorta. The kidneys were slightly enlarged, but not changed. The lungs were over-filled with blood. Only five cases had been published.

Hr. Hirschfeld remarked on the case that the lymph glands were normal. The spleen showed diminution of the follicles, with hyperplasia of the pulp; normoblasts and myelocytes were present in the blood of the spleen. The bone marrow was red through engorgement; the quantity of normoblasts was not greatly increased. Hyperplasia of leucocytes. The chief feature was the change in the bone marrow.

Hr. Max Michaelis was of opinion that not five but many cases of plethora vera had been published, but only five with autopsies. Possibly the disease had some connection with impeded respiration.

Hr. Mohr had seen eight cases in three months. The patients were not cyanotic but flushed; there was no swelling of either spleen or liver. In three the patients had had to do with carbon monoxide. The number of red blood corpuscles in his cases oscillated between seven and eleven millions.

Hr. Westenhoeffer observed that the discussion showed the confusion that reigned as regarded the views on the subject. The cases related by the speakers did not belong to the category of those reported. In those there was absolutely nothing of impeded respiration, of carbon monoxide poisoning, or of concomitant disease. The sole cause of the plethora was the change in the bone marrow. They were cases of myeloplastic polycythemia, the true plethora vera of the older authors.

AUSTRIA.

Vienna, Sept. 29th, 1907.

DIAGNOSIS OF CEREBRO-SPINAL MENINGITIS.

THE differential diagnosis of sporadic "stiff neck" has been puzzling the profession for some time, and every experiment and expedient has been resorted to with the real object of solving the problem. Hölker records 15 cases of this disease, and only six of them responded to the bacterial test during the first week of the illness. In other two cases of the 15 the test was positive after one week's duration of the disease. The remaining seven never responded to any test, although the spinal fluid was examined long after as well as during the illness.

Recently a new theory for the differential diagnosis has been supposed to be established in the state of the lymphocytes in the liquor cerebro-spinalis.

Hölker thinks this rather speculative, and ought to be entertained with caution.

The syphilitic or para-syphilitic and tubercle are the two closely allied diseases which require to be eliminated from the cerebro-spinal meningitis. He finds the same leucocytes in simple meningitis and undoubted tubercle as in cerebro-spinal meningitis, and affirms that the latter has a great number of forms among the white blood corpuscles.

He concludes that the specific coccus is too late in its appearance for any practical use that can be made with it, even when it is found.

The Chronicity of Icterus is Hæmatic.

Benjamin and Sluka, after long and careful examination of icterus, have come to the conclusion that the disease is hæmatic and transmissible from father to son. In several cases which they have observed, no physical or anatomical difference could be found in the organs of the body, but they have found the disease ameliorated or attenuated in the third generation when the grandfather, father, and son were examined; the latter had the disease in a less intense degree than the grandfather.

In the child the icterus was decidely less, the urobilin and urobilinogen diminished, the hæmatoporphyrin and cholic stools were entirely absent. The hæmatic changes are the most notable; the red blood corpuscles are fewer, but the individual erythrocyte holding a surplus of hæmoglobin or poikilocytosis produces a blood anomaly, which leads them to believe that the production of the blood or some noxa is the disturbing factor in the production of icterus. The first exciting cause seems to be the destruction of the erythrocyte, while the increase of the spleen in father and son acts as a "spodogener" in accomplishing the destruction of the red blood corpuscles.

Balantidium Coli Typus Malmsten.

Glaessner showed microscopic preparations of a living parasite taken from the stools of a patient suffering from amœban enteritis. The protozoon was very mobile, and could be easily distinguished as the balantidium coli, measuring 0.01 by 0.07 millimetres and having an oval appearance. The body is covered with a fine hair which assists it in its boring and oscillating motions when moving forward. It is usually transmitted to man through the dejections of pigs, and carried to the intestine of the human being by green tubers and vegetables. The usual therapeutics are small doses of calomel from 0.05 to 0.1 of a gramme, with quinine, extractum filicis maris, carbolic acid in pill and ice water clysters. The latter is the more effective, but it has to be used boldly with the other adjuncts.

Obituary.

Another of Austria's medical philanthropists has passed away in the person of Dr. Anton Loew. An alumnus of Vienna University he studied under Oppolzer, graduated and, according to the custom of the day, travelled over Europe. On his return he built and equipped a hospital in 1881 with the latest improvements of the time, which gave an impetus to the progress of medical science in Austria. He was associated with Billroth in founding the Red Cross, and was consulted in the erection of all hospitals in the Empire.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Resignation of Dr. Rutherford, Crichton Royal Asylum.—It is announced that Dr. Rutherford has resigned the post of Superintendent of the Crichton Royal Institution, Dumfries, which he has now occupied for nearly a quarter of a century. General regret will be felt that reasons of health have compelled him to take this step. Since he received the appointment he is now about to demit, the Crichton Asylum has been greatly enlarged, thanks to his unremitting energy. The pauper patients have been removed from the neighbourhood of the institution, and placed in a separate asylum in the grounds, which extend to 800 acres. A handsome memorial church has also been erected, and the country house of Friar's Carse, formerly the property of Mr. Crichton, the founder of the institution, has been purchased. All these improvements have been carried out at the instigation of Dr. Rutherford, and their magnitude may be judged of when it is stated that together they cost over £110,000. Dr. Rutherford was born in 1840, and after studying his profession in Edinburgh and on the Continent, he returned to Scotland in 1866 with the intention of entering upon general practice. He translated Griesenger's "Mental Diseases" for the new Sydenham Society, and this evidence of the direction in which his tastes lay led to his being offered an assistantship in the Birmingham Asylum. In 1870 he succeeded the late Sir John Sibbald as Superintendent of Argyll and Bute Asylum, and thence was translated to the large asylum of Lenzie. It was in that capacity that his introduction of recent methods of treatment—extension of employment and freedom for the patients—won for him general recognition as an asylum administrator. His work attracted much attention all over the world, and he received the honorary membership of a number of foreign Psychological Societies—French, Belgian, Italian, and American.

Problem of the Inebriates.—The Corporation of Glasgow have issued their sixth annual report on the working of the Girgenti Inebriate Reformatory, which is licensed for females only, and has accommodation for 58 inmates. The report covers the year 1906, and has been delayed in consequence of an abortive attempt by the Corporation to have the Inebriates Act amended. In consequence of their failure to do this and also on account of a reduction of the Treasury grant from 10s. to 7s. 6d. per inmate per week, they have resolved to discontinue this reformatory. On December 31st, 1905, there were 41 inmates, and during 1906 there were 17 fresh admissions, the total number since the opening of the home being 130 patients. The average age of the 1906 admissions was 27 years. The inmates are employed at farm work, sewing, knitting, etc.; a number of them, accompanied by attendants, are permitted to visit their friends for a day. Writing and receiving letters is permitted. Gratuities of 3d. a week for good behaviour, and 3d. a week for work done, are allowed. Concerts and musical evenings are got up, and educational facilities are afforded in the evenings. Nine patients were allowed out on license under the charge of suitable guardians. Of these, three relapsed and were re-admitted; two did well, but were re-admitted for accidental reasons; two did well, and their sentences expired while under license; two are at present doing well. A large number of escapes took place, which is no doubt partly due to the fact that the institution is not walled in. Twenty-four inmates were involved in attempts to escape; two are still at large. The expenditure amounted to 24s. per inmate per week, of which 10s. 7d. was provided by the Treasury, and the balance by the Corporation. Dr. Cunningham, Medical Officer, states in his report that three inmates are, in his opinion, border-line cases, and may require to be transferred to an asylum. Four inmates have required treatment for epilepsy. Dr. Cunningham adopts the following classification of the patients:—(*a*) 1st class, excitable hysterical patients with inability to control temper and passions; (*b*) 2nd class, weak-minded, imbecile patients, who are indifferent to their surroundings, and make no attempt to conceal their position; (*c*) 3rd class, accidental or periodical drunkards, in whom a fit of depression precedes a bout; they have small resisting power, and are easily led for good or bad; (*d*) 4th class, patients in poor physical condition and mental health, from unhealthy surroundings, bad food, neglected education; the drinking bout is of long duration. Of the 130 patients admitted since the home was opened, the distribution among the different classes was as follows:—(*a*) Hysterical patients, 18; (*b*) weak-minded, 17; (*c*) accidental drunkards, 22; (*d*) chronic inebriates, 73. Dr. Cunningham regards the chronic inebriates as practically hopeless. The treatment is essentially the same as that of mental disorders, the object being not merely to stop drinking, but to suppress the craving.

Two years ago drug treatment was begun, the remedies used being atropin. sulph. gr. 1-100 daily, and a mixture containing sodium, quinine, ammonium, and aloin. It has proved an absolute failure. Turning to the tables of discharges for 1904, 1905, and 1906, we find the after histories of 54 patients. Of the 29 who were discharged during 1904, all except seven had further convictions against them during 1905 and 1906, and therefore must be regarded as failures. Of the seven who escaped conviction one married and has relapsed, one is unknown, one is dead, one is in the poorhouse, one did well while on license, two continue to do well. Of the 22 who had further convictions against them, one is said to be in domestic service and doing well, another did well but is dead, and another is a farm servant. That is to say, two out of 29 remained cured for at least two years, and two more did fairly well. Of 16 patients discharged during 1905, seven escaped further conviction, three are known to have relapsed, one is in Canada, and three are doing well. Only one of those convicted for drink is known to be doing well now. Of the nine patients discharged during 1906 only three are known to be doing well. Excluding the last year, we thus have total discharges of 45; of these five are cures at the end of 18 months to 2½ years; four have had subsequent convictions, but are doing well now. These figures need no comment; they tell plainly enough how little prospect there is of reforming the class of patient who is admitted to an inebriate home. It is hardly to be wondered at that the Corporation of Glasgow have resolved to discontinue the Girgenti Retreat.

EDINBURGH POST-GRADUATE COURSE.—This course was brought to a termination on September 27th, and has proved even more successful than its predecessor of last year. On September 13th the President and Fellows of the Royal College of Surgeons gave an "At Home" to members of the course, and the post-graduates, in their turn, showed their appreciation of the classes by entertaining their teachers to dinner at the Caledonian Station Hotel on the 26th.

BELFAST.

THE LATE DR. MULLAN, OF BALLYMENA.—Dr. Andrew Mullan, of Ballymena, co. Antrim, who died last week at Larne, was well known for many years in his county. He graduated in the old Queen's University in 1866, taking the degrees of M.A. and M.D. He took a widespread interest in various religious and philanthropic organisations, and will be much missed in his district, where he was highly respected.

PUBLIC HEALTH.—The Public Health Committee of the Corporation is following up its campaign of bill-sticking by issuing a card of instructions as to precautions to be taken against tuberculosis, and proposes to send this card to schools and factories.

HOUSE REFUSE.—The question of ashbins instead of ashpits was discussed at the last meeting of the Committee, and it was stated that the annual cost of the fortnightly cleansing of 80,000 ashpits was estimated at £31,000, while the removal of the contents of a similar number of ashbins would be less than £20,000. The bin system has been in use in Liverpool for many years, apparently giving satisfaction, and it is probable that it will be introduced into Belfast.

The number of cases of cerebro-spinal meningitis notified last week was only four, and one death occurred. The total death rate from zymotic diseases was 1.8.

LETTERS TO THE EDITOR.

WHERE ARE THE POLICE?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your attention has doubtless been called to a new patent medicine, said to have been derived from ancient Egypt. Marvellous virtues are claimed for it, and it is retailed to the public at one shilling and a penny per box. Now when one looks at the way this nostrum has been advertised in the public newspapers, it is evident that an enormous sum must have been already spent in advertising. Its broadsheets are signed by a name that suggests some sort of a connection with other more or less notorious quack remedies. To the ordinary medical man this pernicious trade venture is a cruel and fradulent imposture, to be paid for in the long run with tears and blood by a deluded public. How is it that newspapers with any claim to respectability can descend to take money from these rogues? How is it that Scotland Yard and the Home Office permit such frauds to go unchecked? There is hardly one of these notorious quack remedies, which have brought millions of money to their owners, that could not be successfully prosecuted for conspiring to obtain money under false pretences. Where are the police?

Yours faithfully,
AN IRATE PRACTITIONER.

Brighton.

OBITUARY.

PROFESSOR CHARLES STEWART, LL.D., F.R.S.

BY the decease of Professor Charles Stewart, F.R.S., which occurred on Friday last, after a somewhat protracted illness, the Royal College of Surgeons of England has lost an official who has held the office of conservator of the museum for the past 23 years.

After attending as a medical student at St. Bartholomew's Hospital, Professor Stewart obtained the qualification of membership of the Royal College of Surgeons in the year 1862. He was admitted a Fellow of the Linnean Society in 1866, and became President of the Society during the years 1890 to 1894, and in the following year served as Vice-President. Professor Stewart was also a Fellow and Vice-President of the Royal Microscopical Society, and became one of its honorary secretaries in the year 1878. He was treasurer of the Anatomical Society of Great Britain and Ireland from its foundation until 1891. During the period 1894-1897 he held the office of Fullerian Professor of Physiology at the Royal Institution, and delivered several evening lectures at the same place. He was admitted a Fellow of the Royal Society in the year 1896, and obtained the Honorary LL.D. of Aberdeen University.

Before being appointed Conservator of the College of Surgeons' museum, Professor Stewart was Curator of the museum of St. Thomas's Hospital, Lecturer on Comparative Anatomy, and Joint Lecturer with Professor John Harley, on Physiology at that institution. He was subsequently appointed Professor of Biology and Physiology at Bedford College. In the year following his appointment at the College of Surgeons he was elected Hunterian Professor of Human and Comparative Anatomy, and held this lectureship until the year 1894.

The true value of Professor Stewart's scientific work is not to be judged solely by his writings, which, in spite of the vast extent of his knowledge gained from personal observations, were comparatively few in number, but it is to be seen rather on the shelves of the college museum in the unrivalled series of preparations and dissections by which he sought, in continuation of the work of previous conservators, to illustrate important phases in the evolution of the organic world, and thus to amplify the original scheme of John Hunter, whose collection forms the nucleus of the college museum. Professor Stewart was also a master in the art of lecturing. His easy and lucid style, combined with a rare power of swift and effective drawing on the blackboard, would have made his lectures notable, quite apart from the peculiar personal charm of his delivery.

FRANK J. LOCHRANE, M.D., Ch.B.Glasg.

WE regret to record the death, which occurred on September 21st at Derby, of Dr. Frank J. Lochrane, after a few weeks' illness. Dr. Lochrane, who was only 29 years of age, showed great promise as a member of the profession. He was a native of Glasgow, and studied at the University in that city, at Edinburgh, Vienna, London, and Dublin. He graduated M.B. and Ch.B. in 1901, and three years later took his M.D. degree. His first appointment after qualifying was that of house physician and surgeon at Glasgow Royal Infirmary, and he afterwards became house surgeon at Peterborough Hospital. He went to Derby in 1905, being appointed house surgeon at the Women's Hospital on the death of Dr. Henderson Pounds, to whose private practice he also succeeded. A few months ago he was elected a member of the honorary staff of the Derbyshire Royal Infirmary, in the capacity of gynæcologist. He was unmarried.

REVIEWS OF BOOKS.

ULCERATION OF THE CORNEA (*a*)

In writing a book such as this the author gives us good evidence, if any were needed, as to how our bacteriological knowledge of ulcers of the cornea is maturing. While not failing to give a good clinical picture of each form of ulceration, Dr. Macnab devotes most of his efforts to establishing, as far as possible, a classification of corneal ulcers founded on the bacteriological findings and the treatment he has found most suitable for each.

In Chapter I. we find the usual methods of examination described. Dr. Macnab gives a preference to Hartnaek's loupe, but we think Berger's after a short trial becomes very easily managed, and has the advantage of leaving our two hands free to manipulate a lens for oblique illumination and fixing the lids. He tells us the sensibility of the conjunctiva, lid margins and cilia is greater than that of the cornea, and on page 25 "it must be noted that the sensibility of the cornea is not very acute, and certainly is quite dull when compared to that of the conjunctiva and lid borders." These are pronouncements hard to reconcile with clinical and personal experience. In Chapter III. hypopyon keratitis, or pneumo-coccal ulcer, as Dr. Macnab prefers to call it, is fully described, a translation of Saemisch's description being given. The possibility of anterior synechia taking place without a complete perforation of the cornea, due to the perforation of Descemet's membrane, is pointed out as a fact. Some of the difficulties of the diagnosis and the study of the life history of the pneumoccus are here given. For the active treatment of the infiltrated margin of the ulcer Dr. Macnab advises either the electric cautery or pure carbolic acid, but before doing so he lays stress on the importance of thoroughly scraping away sloughs and loose epithelium to facilitate the complete and direct application of the cautery.

Ulcers due to streptococcus, pyocyaneus, Friedlander's B., B. coli commune, staphyloccus, etc., are considered in Chapter IV. In subsequent chapters we find ulcers due to infection from the various forms of specific conjunctivitis, Mooren's and Zur Nedden's ulcers described. Chapter X. is a useful one. It takes us over the bacteriology of organisms found in corneal ulcers.

In the last chapter are described the operations for removal of the lacrymal sac, Saemisch section, and what the author has christened the "Corneal Plastic Operation." In treating of the first-named operation Dr. Macnab does not give any advice as to the anæsthetic used. He refers to the troublesome hæmorrhage generally met with, and advises as a remedy for it the use of the Müller and Axenfeld retractors. These are undoubtedly indispensable, but we cannot say that they always act as efficient controllers of the blood flow, whereas, we have reason to appreciate the good results of subcutaneous injections of cocain, or eucain, and adrenalin both as to anæsthesia and bloodlessness. The corneo-plastic operation, more recognisable as Kuhnt's transplantation of conjunctiva, is well described, and is deserving of more general use as a preventative of staphyloma corneæ and in hastening the process of healing.

There are a few errors that are inexcusable, perhaps, such as the spelling of Mr. Priestley Smith's name and that of Professor Uhthoff, but these by no means forbid a full welcome being given to Dr. Macnab's efforts to lead us on to a more scientific knowledge and classification of corneal ulcers.

RECTAL DISEASES (*a*).

We have received for review the third edition of Mr. Harrison Cripps' well-known work on diseases of the rectum and anus. The book also includes the fifth edition of the Jacksonian prize essay on cancer of the rectum. This portion of the book has been rewritten, and to it has been added a table of 380 consecutive cases which occurred in Mr. Cripps' private practice. The book as a whole furnishes a most valuable monograph on rectal disease.

The author's comments on the value of a speculum as an aid to diagnosis of rectal disease, especially when used in the surgeon's consulting room, is short and to the point:—"It will generally end in a fluid motion on your couch, and the rapid vanishing of the patient who is seldom reclaimed." We should like, however, to find some reference to the sigmoidoscope. If this instrument is of no value for diagnostic purposes, then this fact should be stated as a guide to Mr. Cripps' readers. If it is of value, then a description of its working might with advantage be included. Personally we regard it as calculated to be of as great value in these cases as is the electrically-lighted cystoscope in cases of disease of the bladder.

As is proper, the nature and treatment of the various forms of hæmorrhoids receives full attention, as do such subjects as prolapse, abscess, fissure, stricture. In discussing the treatment of pruritus ani, the operation for this distressing condition devised by Sir Charles Ball has not received the mention to which its novelty and value appear to entitle it.

The Jacksonian essay on rectal cancer which has been added in the present edition, and which can also be obtained as a separate publication, occupies the last nine chapters of the book. A long chapter is devoted to the etiology of rectal cancer, and as the etiology of this form of cancer differs in no particular from that of any other form of cancer, the chapter is practically devoted to the etiology of cancer wherever it may occur. This involves a great deal of discussion, which, however much it may have been suitable in the case of a prize essay, is, we cannot help thinking, entirely out of place in a work on rectal diseases. As well might the chapter on rectal abscess be prefaced by a long discussion on the nature and source of pyogenic organisms. Mr. Cripps' book is of quite sufficient length and importance to enable all unnecessary matter to be dispensed with, and therefore we should like to suggest that in a subsequent edition its size be somewhat curtailed by the exclusion of such matters as the etiology of cancer.

EYE INJURIES (*b*.)

This volume comprises post-graduate lectures delivered by Dr. Ramsay which have been rewritten, and are now published "in the hope that they may prove helpful to general practitioners." Their scope being clinical, all discussion of theories has, as far as possible, been avoided. One is at once struck by the handsome way in which the book is produced—the paper being unusually rich, the print large, and the illustrations, of which there are about sixty, some coloured, are unusually beautiful. Dr. Ramsay has a nice clear style, and makes his remarks interesting by the relation of cases which have come under his observation. The advice given to the general practitioner is reliable, and cannot but be of service to those readers for whom it is mainly meant. We are glad to see in Chapter VI. that Dr. Ramsay has had experience of injecting argyrol into the anterior chamber of eyes which have become infected from perforating wounds, those desperate cases that call

(*a*) "On Diseases of the Rectum and Anus, Including the Fifth Edition of the Jacksonian Prize Essay on Cancer." By Harrison Cripps, F.R.C.S., Senior Surgeon to St. Bartholomew's Hospital, &c., &c. Third edition. London: J. and A. Churchill. 1907.

(*b*) "Eye Injuries and Their Treatment." By Maitland Ramsay, M.D. Pages 210. Plates 25. Glasgow: James Maclehose and Sons. 1907. Price 18s.

for prompt and radical treatment. The reviewer's experience is limited to one case where panophthalmitis was fully expected. A few drops of 5 per cent. argyrol injected into the anterior chamber acted so quickly that next day the hypopyon had disappeared, the pupil was well dilated and chemosis and pain were gone. After removal of the soft lens useful vision resulted.

In diagnosis of sympathetic irritation the author lays stress on the spindle shaped enlargement of the blind spot as demonstrated by Bjerrum's screen. He takes this sign to mean congestion of the optic disc. At the same time a low degree of myopia may be present. Without wishing to account for these signs Dr. Ramsay tells us that they disappear on removal of the exciting eye. Reading on we come to sympathetic inflammation, and we find ourselves in a technical discussion as to its pathogenesis. Six rules afford reliable and concise guides as to when to enucleate and when not to enucleate.

Dr. Ramsay does not approve of the modern tendency of confining ourselves to local treatment only, with which we are quite in accord, but we think he goes somewhat far in the opposite direction in the following:—"Again, in a case of keratitis, most gratifying results are often obtained by following the old-fashioned plan of blistering the eyelids with solid caustic; and in iritis, when the disease is tending to relapse time after time, the application of a blister often brings about such a change that recovery goes on afterwards without interruption. A more pronounced result still is obtained if the blistered surface be kept open by the application of an irritating ointment or by D'Albespeyre's paper, and in all deep-seated chronic inflammation an open blister contributes largely to the means of a cure. When the inflammation is due to syphilis, the presence of an open sore is, in my experience, most helpful, and therefore, in such instances, I have not the slightest hesitation in inserting a seton in the nape, and keeping it there for several months. So strongly, indeed, am I convinced of the value of such measures that I feel that those who do not fully avail themselves of them deprive their patients of an important source of help."

Inasmuch as most general practitioners have their own ideas as to what an "Alterative Pill" or "Iron Pill" ought to be, we think the sixty pages devoted to the Pharmacopœia of Eye Diseases might have been curtailed considerably. We congratulate Dr. Ramsay on the masterly work he has produced and his publishers on the way in which they have accomplished their part.

PRACTICAL ANÆSTHETICS (*a*).

THE author states that the object of this little book is to furnish a short guide to those who have not the leisure to study other large manuals on the subject. The work is divided into eight chapters, and runs into over 170 pages. When a surgical operation has to be performed we consider the selection of an anæsthetic and its administrator is all-important—sometimes far more important than the operation itself, as regards danger to the patient. It is very pleasant indeed for a patient about to undergo a serious surgical operation to be able to sink calmly and safely into the mysterious sleep of insensibility, trusting only in the goodness of his Maker and the skilful knowledge of his operator and anæthetist. Practitioners too often are called on in a hurry to administer an anæsthetic for an emergency operation, and frequently without much special knowledge of the subject. We consider no one should be allowed to adminster an anæsthetic unless such a person has had some preliminary training in the administration of all descriptions of anæsthetics in a hospital, under the direction and supervision of a skilled anæsthetist. The author describes the many difficulties and dangers of anæsthesia, and gives much practical information to the beginner, as regards what to do, and what to avoid. He does not appear, however to be aware that the ether inhaler, so often called by Clover's name, was in reality a modified copy of the original ether inhaler, adapted by Ormsby, of Dublin.

We advise all who either now adminster anæsthetics or who hope to do so, to purchase this little book, as it will give them many useful hints on the subject.

LECTURES ON CLINICAL SURGERY (*a*).

WE have read through these practical clinical lectures and addresses, which the author tells us have already appeared in the columns of the *British Medical Journal* and the *Clinical Journal*. They are printed as they were delivered, in rather a colloquial style, so as to emphasise the lecturer's meaning to his class. The lectures comprise such practical subjects as: The Course of Intra-abdominal Inflammation, on the Recognition and Management of Intestinal Obstruction, Carcinoma of the Breast and its Spread into the Lymphatics, Varicose Veins, etc. The lectures are not only interesting and practical, but are most readable, and many a young operating surgeon or general practitioner will derive a great deal of sound useful information from their perusal, which will be of service to him in his practice, where difficult and doubtful cases come before him.

GOUT (*b*.)

THE third edition of this well-known work hardly calls for a detailed notice. It is written in the clear and lucid style that one has learned to associate with all that comes from the author's pen. Yet the book does not simply mark time in our scientific attitude with regard to gout. Dr. Luff herein (p. 64) formally abandons his theory of the renal origin of the malady, with which his name has been so long associated, and he now adopts the view that a bacterial toxin is probably the primary cause of gout. This change of opinion serves to illustrate the obscurity that still surrounds the etiology of this important disease. For our own part we are inclined to think that hardly enough stress is laid by investigators upon the *tertium quid* in the shape of some peculiar predisposition in the constitution of the patient. In discussing treatment we note that the use of the galvanic current is advocated in conjunction with massage in order to promote absorption of œdematous infiltration and deposits. Similarly cataphoresis of gouty joints with potassium bicarbonate or lithium iodide is advised. The local electrical treatment of gout is a branch of therapeutics that deserves more attention that it receives at present from medical men. Patients suffering from acute or subacute attacks of gout are warned against resorting to the Turkish bath. The book is well published, it goes without saying, and it is the plain duty of every physician to master its contents.

TUBERCULOSIS, THE REAPER. (*c*.)

THE fact that this popular treatise on the tuberculosis problem has now reached a second edition after having been widely distributed throughout France by the order of the Minister of Public Instruction affords ample evidence that the work at least has been appreciated, and it may be hoped will prove of lasting service to the people of France. It is clear that if tuberculosis is to be eliminated from civilised countries, it can only be by the instruction of the masses and the acquiescence of citizens, and particularly of parents in the practical conduct of such anti-tuberculosis

measures as Dr. Barbary so well enunciates and explains in his manual. The work is constructed on common-sense lines and can be readily followed by any intelligent layman. In a simple but forcible manner, he explains the nature, causation; pathology, and clinical manifestations of pulmonary tuberculosis and discusses the principles of prophylaxis and treatment in a manner more adapted for the physician than the man in the street. The book is perhaps more suited to the family practitioner than to the unscientific head of a household. Particulars are given of a number of sanatoria, and climatotherapy and the use of mineral waters are discussed. In the closing chapter the anti-tuberculosis campaign as conducted in France is briefly described. There are a number of illustrations, and two maps roughly indicating the geographical situation of the chief sanatoria in Germany and Belgium. Although there is a table of contents, there is, in accordance with the unpardonable custom of French authors, no index.

MATERIA MEDICA AND PHARMACY. (*a*)

This remarkably compact and well-digested compendium of materia medica and therapeutics is such an old friend that comment is almost unnecessary. This edition has been carefully revised and brought up to date, and this is especially the case in respect of organotherapy, even that interesting departure in treatment, the employment of the now famous opsonic index, receiving a full meed of attention. We would respectfully urge the author to abandon the use of the term "tubercular" (which is, strictly speaking, an anatomical term) in lieu of "tuberculous," *e.g.*, derived from tubercle.

The work will be found an extremely convenient work of reference by practitioners, more particularly now that the study of materia medica and therapeutics has unhappily been placed in the background of medical education. Prescribing, it has aptly been remarked, is becoming a lost art, and many medical men affect scepticism in regard to the use of medicinal agents, mainly on account of the difficulty they experience in handling them—an art that is of the highest importance in the daily routine of practice, as much as, indeed, a knowledge of anatomy and physiology. The latter, indeed, are but the means to an end, and that end is therapeutics. Patients want to be *treated*, and diagnosis, after all, is, or should be, only a preliminary step in that direction.

WRIGHT'S MEDICAL ANNUAL.

This useful publication is so well known to the profession and so justly valued, that there is little need for comment on each successive issue. This year's number contains some sixty pages more than that for 1906, and the number of contributors is also a little increased. Among the new contributors are Mr. Sampson Handley, who discusses cancer in a notable article, an excellent summary of present knowledge on the subject; Mr. Robert Jones, who writes on Nerve Anastomosis and Nerve Grafting; Dr. Batey Shaw, who writes on Diseases of the Ductless Glands, and Dr. Whitridge Williams, who writes on the Toxæmias of Pregnancy. It will be seen that the editors spare no pains to obtain writers of special authority in their various subjects. We have tested the book on many points, and while noting a few omissions, we have failed to find any serious flaw. As is almost inevitable, there is a certain lack of proportion between the different articles, and a certain want of uniformity of treatment. Some writers give mere abstracts of recent literature, while others contribute critical articles of original value. Taken altogether, however, the book is invaluable to the general practitioner, as he has long ago learnt. We deprecate the tendency to increase the bulk of the book, though, as the price remains the same, it would be ungrateful to grumble.

THE SIGMOIDOSCOPE. (*a*)

This little book gives a good working description of an instrument which ought to be in far greater use than it actually is. The form of sigmoidoscope which the author recommends is that originally devised by Professor Strauss, and which he has slightly modified. He emphasises the importance of obtaining the proper and best pattern when purchasing an instrument, as there are several poor imitations of it on the market.

Having described the mode of using the instrument, the author proceeds to describe the appearances seen by its aid in various pathological conditions. There are also several illustrations, which, however, would be of more value if they were coloured, but we presume the increased cost would be too great for a book which must necessarily meet with only a limited demand. We can cordially recommend the little work to any one who is desirous of acquiring a knowledge of the mode of using a useful instrument.

PALMER ON MASSAGE. (*b*)

The appearance of the third edition of this book testifies to its excellence as a handbook. The wide experience of the authoress in the massage department of the London Hospital has taught her what are the essential points required by a learner of the act. Accordingly we find a reference to anatomy and physiology that is sufficiently full without being burdened with unnecessary details. There we may see good illustrations and tables, and chapters are added on the Nauheim treatment and massage of children. On the whole this is one of the best special works of the kind with which we are acquainted, and a nurse requiring a handbook of massage would do well to choose a Palmer's book.

Plague at Oran.

Plague has broken out at Oran. According to the Paris papers, there have already been two deaths, one of a porter, and the other of the wife of a railway official. The number of cases in one journal is reported as four, and in another as 11. The centre of infection is in the store sheds of the Chamber of Commerce, where the victims were at work, and where rats are said to have been found. Admiral Philibert has announced that all war and transport ships belonging to the State have left Oran and proceeded to Mers-el-Kebir. The base of operations has been transferred from Oran to Algiers.

Notification of Births.

The Local Government Board have just issued a circular to local authorities explaining the new Notification of Births Act. The object of the measure, which will only be in operation where it has been adopted by the local authority with the consent of the Board, or has been declared to be in force by the Board, is to provide a speedy means whereby information of the birth of a child may be given to the medical officer of health of the local authority, so that, if necessary, advice may be given to the mother in regard to the rearing and nurture of the child. The Board observes that there is no occasion for imposing upon parents and others the obligation of notifying births in the special manner provided by the Act unless steps are taken to carry out the ultimate object of the measure, viz., the giving of advice and instruction to those who have charge of the infants, and in ordinary circumstances the Board would not be prepared to consent to the adoption of the Act unless it appeared that arrangements had been made for this purpose. These arrangements would usually be best carried out by local agencies under the medical officer of health. The Board trusts that the local authorities will consider the question of adopting the Act and of co-operating with any agency that may exist, so as to secure its successful operation.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT PATHOLOGICAL LITERATURE.

Howell's Granules.—In 1890 Howell pointed out that in the blood of cats following a hæmorrhage large numbers of the red corpuscles may contain a single good-sized piece of nuclear matter, too large to be called a granule, and having the shape and appearance of a large nucleolus. Since that time other observers have studied them, and doubt has been expressed as to whether they were nuclear in origin, or merely basophile granules, such as are met with in many forms of anæmia. Morris (*Johns Hopkins' Hospital Bulletin*, July, 1907, page 199) now describes them for the first time as occurring in human blood, in various cases, such as typhoid fever and pernicious anæmia. He has also found them in the blood of two fœtuses, and believes that they appear always in association with increased blood formation. As found in the blood of rabbits poisoned with pyrodin, he describes the structures as round or oval in shape, and almost invariably eccentrically situated in the containing corpuscle. The outline is well defined, and occasionally there is noted a paler zone in the protoplasm of the cell surrounding the nuclear particle. Unlike basophilic granules, they take up a purple colour like that of the nucleus with Romanowski's skin. M.

Cephalic Tetanus.—Friedlander and Meyer have observed a case of cephalic tetanus (*Deutsche Med. Woch*, 1907, No. 28) in which the spasms and paralysis remained limited to a very small muscular region, but in which the intensity of the disease was nevertheless great. The duration of the period of incubation and the entire course of the disease were very long, but the case ultimately ended fatally. The facial paralysis was very distinct, and involved the abducent, the oculo-motor, and the trochlear nerves, as well as the facial nerve itself. The authors consider the various possible causes of this paralysis, and conclude that the most likely underlying pathological change is an ascending neuritis. M.

Orthostatic Albuminuria.—According to the investigations of Porges and Pibram (*Deutsch Archiv. fur Klin. Med. Bd.* xc., p. 367) it is probable that orthostatic albuminuria is caused by changes in the kidney circulation. General influences, such as changes in the general systemic circulation, appear to be without any real influence. Amongst the local conditions which lead to venous stasis in the kidneys they include an increase in abdominal pressure caused by changes in the position of the body, and changes in the position of the kidneys themselves. They believe also that spasm of the small arteries of the kidneys may in many cases also cause albuminuria. The knowledge that such spasm is present in the living is of course only obtained indirectly, and is, as a rule, merely the result of exclusion of other causes. M.

Vaquez Disease.—Hnàtek (*Casopis likaru ceskvet*, 1907, p. 687) has investigated a case of idiopathic polycythæmia occurring in a labourer aged 56, who had suffered during three years from dyspnoea, giddiness, and a dark red colour in the face. As a child he had suffered much from epistaxis and hæmorrhage from other mucous membranes. Objectively one found marked facial cyanosis; the mucous membrane of the mouth of a deep red colour; marked carotid pulsation; dilated superficial veins; blood pressure 150 m.m. Hg.; and a splenic tumour extending down as far as the crest of the ilium. The number of red cells was fourteen million per c.m.m.; the hæmoglobin reached 188 per cent.; and the white cells 36,000 per c.m.m. The urine was highly albuminous, After a period of three months no change was found in the condition. The author discusses the etiology, and suggests that it may be due to defective destruction of red cells, owing to an absence of the suprarenal secretion. Experimentally, injections of adrenalin have been found to cause extensive blood destruction. Various remedies were made use of in the case, but without avail. M.

Blood Formation in the Liver and Spleen.—During fœtal life the liver and spleen have hæmopoietic functions, and pathologically during adult life it seems likely that they resume these functions, as, for example, in pernicious and other severe anæmias. In order to ascertain whether such a reversion in function can be induced experimentally, Morris has produced anæmia in rabbits. (*Johns Hopkins' Hosp. Bulletin*, July, 1907, page 200, etc.) by the subcutaneous injection of pyrodin. The conclusions at which he arrives are as follows:—(1) The anæmia caused by pyrodin is one with a high colour index, and results from injury to certain of the red cells, which are then removed from the circulating blood by phagocytes in spleen, bone-marrow, and liver. (2) The increased blood destruction leads to compensating increased formation. (3) Heightened activity of the hæmopoietic functions of the bone-marrow is met with, and myeloid elements occur in the spleen and occasionally in the liver. (4) The changes in liver and spleen are similar histologically to those seen in normal rabbits' embryo. From this it seems likely that the spleen and liver had resumed their hæmopoietic function. (5) Hæmosiderosis of organs occurs as in pernicious anæmia. M.

Phagocytic Action of the Alveolar Cells.—Briscoe (*Journal of Pathology and Bacteriology*, October, 1907) reports a very elaborate investigation of the nature and functions of the alveolar cells of the lungs. The following are the more important of his conclusions:—(1) The mononuclear cells of the alveoli are powerful phagocytes. (2) The phagocytic action of these cells depends on an opsonin. (3) With a mild infection, by the help of an opsonin, and without the aid of leucocytes, the alveolar cells can free the lungs of organisms. (4) If the infection is more virulent, the leucocytes give active assistance. (5) Phagocytosis is more rapid when the animal infected has been previously immunised than when a normal animal is employed. (6) For some time after infection phagocytosis is limited to the alveolar cells. (7) The bronchioles, not being lined with phagocytic cells, are at a disadvantage as compared with the alveoli in regard to an infection spreading downward. R.

An Anti-Gonococcic Serum.—Rogers and Torrey (*Journal of the American Medical Association*, September 14, 1907) report the mode of preparation of, and the results of treatment by, an anti-serum for gonorrhœa. Rabbits were at first used for preparing the serum, but as it was found that rabbit serum, though sufficiently potent, might also be very toxic, sheep were afterwards substituted. Full-grown rams were found most suitable, and ten injections were given intra-peritoneally. The first inoculation consisted of the twenty-four surface growth from eighteen square inches of solid culture medium, emulsified in about 30 c.c. of physiological salt solution, and heated for half an hour at 65 deg. C. After an interval of about a week the second injection was given, consisting of the growth from about thirty square inches, emulsified and heated as before. The third inoculation consisted of about eighteen square inches of *unheated* growth, and thereafter increasing doses were given up to a maximum of about forty-five square inches of unheated growth. After nine or ten inoculations, a little blood was drawn and tested for agglutinins. If agglutinins were present in quantity the animal was regarded as highly immunised, and it was bled to death, the serum being collected. The gonococcus used for making the inoculations was of mixed strains, with the view of producing a polyvalent serum. The serum was administered in doses of about 2 c.c. each. The authors do not regard the serum as having any potency toward acute gonorrhœal lesions, such as acute urethritis, and they do not advise its use in such cases. They furnish sufficient clinical reports as to its use in more chronic gonorrhœal infections, such as arthritis, gleet, cystitis, leucorrhœa, to justify a further trial. The criticism is to be made that the authors do not establish the specificity of the serum as an anti-serum to gonorrhœa. They by no means exclude the possibility, which they do not perceive, that the curative effects of the sheep's serum may be due, not to the action of an anti-serum, but to a vaccination. We do not find any experiments to show that the serum as actually used was sterile of gonococci. Moreover, the therapeutic effects are very similar to those of vaccination by dead gonococci. R.

Causation of Atheroma.—Rickett reports (*Journal of Pathology and Bacteriology*, October, 1907) a series of experiments on the causation of atheroma. It had previously been pointed out that the prolonged administration of adrenalin was almost invariably followed by atheroma of the arteries, and it had been held that this result was due to a toxic action of the adrenalin on the vessel walls. In opposition to this, Rickett held that the cause of atheroma was purely mechanical, viz., the continued high blood-pressure. To put the matter to the test, he tried the effect on the vessels of rabbits of the continued injection of other drugs which have similar effect to adrenalin as regards blood-pressure, though differing from it and from each other in most other respects. With squills, with barium chloride, with tobacco, and with nicotine, Rickett succeeded in producing an atheromatous condition of the vessels. That this change was not due to a merely irritant action seems to be established by the failure to produce it by the continued intravenous injection of potassium cantharidate. This drug was chosen because, though highly irritant, it causes no rise of blood-pressure. R.

Origin of Rodent Ulcer.—Noon (*Journal of Pathology and Bacteriology*, October, 1907) discusses briefly some of the views which have been held regarding the point of origin of rodent ulcers. His seven observations support the doctrine that this form of tumour starts in the malpighian layer of the epidermis, near the necks of the hair follicles, and from the reflection of this layer, which forms the outer root sheath of the hair. He furnishes plates which would be difficult to reconcile with any other opinion. At the same time, the possibility is admitted of another form of tumour, which clinically would be regarded as rodent ulcer, originating in the epithelium of the sweat-glands. No notice, however, is taken of the modern suggestion that rodent ulcer is an endothelioma of the superficial lymphatics. R.

MEDICAL NEWS IN BRIEF

Royal Academy of Medicine in Ireland.

THE annual general meeting of the Royal Academy of Medicine in Ireland will be held in the Royal College of Surgeons, on Friday, October 11th, 1907, at 4.30 p.m., when the annual report will be submitted, and the officers and members of Sectional Councils will be elected. The offices for which candidates may be nominated are:—General Secretary and Treasurer; Secretary for Foreign Correspondence; Presidents of the Sections of Obstetrics, Pathology and State Medicine; Member of Council in the Sections of Medicine, Surgery, Obstetrics, Pathology, Anatomy and Physiology, and State Medicine. A Fellow is ineligible for election on more than two Sectional Councils. No Fellow can be a candidate for election on both Medical and Surgical Councils.

Deportation of an English Lady from America.

A SAD case of suicide and homicidal mania has just transpired by the return to England on the White Star liner "Adriatic," which arrived at Southampton from New York, of a young English lady evidently well connected and with ample means. She is said to be the daughter of a millionaire London banker, and arrived in New York on the "Oceanic" on May 31st last. The poor lady's conduct during the outward voyage was so strange that she was taken to the private sanatorium of Dr. Curtiss at Flushing, Long Island, near New York, where, however, she did not improve in health. On the contrary, she became worse, and ultimately the most luxurious suite on the "Adriatic" was engaged for her, and with an army of attendants and nurses she was taken on board and given in charge of the Commander, Captain E. G. Smith. Painful scenes of violence and an attempt at suicide were made by the afflicted lady prior to the sailing of the ship. The Immigration Commissioner of New York refuses to discuss the case, and would not say whether or not she was being deported by the Immigration Authorities.

A Supreme National Health Authority.

THE proposal has been thrown out that a preliminary conference of the representatives of the Sanitary Committees of the County Councils, County Boroughs, and Municipal Boroughs (Metropolitan and Provincial) and Port Sanitary Authorities of England and Wales, shall be held in London on November 13th, 14th, and 15th, for the purpose of considering the question of the establishment of a permanent Union of the Sanitary Authorities of the Kingdom into a Supreme National Health Authority. As we said last week, the absence of uniformity of action on the part of sanitary authorities generally in furtherance of questions concerning the public health of the country has been recognised for a long time past, and, on account of the diversity of the interests involved, has hitherto been regarded as an almost insurmountable difficulty as well as a cause of much waste of energy and time in attempts to carry out broad measures of sanitary reform. This difficulty may, it is thought, be minimised, if not entirely overcome, by a combination of the respective bodies into one great whole for the consideration and treatment of the hygiene of the nation at large. Many sanitary authorities have already undertaken to send representatives to the conference, and favourable replies have been received from a large number of others. The Chairman of the Executive Committee is Alderman Dr. H. W. Newton, of Newcastle-upon-Tyne, and Mr. Henry E. Armstrong, Medical Officer of Health for Newcastle-upon-Tyne, is hon. secretary.

Bristol Royal Infirmary.

THE *Bristol Medico-Chirurgical Journal* contains some strong comments on the new rules adopted at the Bristol Royal Infirmary. "By what right," says the editor, "do the committee or the governors of the Royal Infirmary presume to dictate to their honorary physicians or surgeons how they shall occupy their life apart from their duties to the Bristol Royal Infirmary? The living governors and their lay committee have neither built nor endowed the institution, and are mainly the inheritors of the generosity of bygone ages, to which they add their quota. So with the medical staff. Here, as elsewhere, they have not made the prestige of the Royal Infirmary; they inherit it from their medical forefathers, but they, too, add their quota to the good repute. The governors inherit the buildings and endowment, and it is theirs to maintain; but so, too, the medical profession inherit the medical prestige, and that is theirs to maintain. But, alas! and here is the pity, the lay governor, realising that there is a prestige attaching to his hospital, considers it is his to manipulate even to the detriment of the medical staff. If you serve our institution, they say, you must have your charitable wings clipped and go lame. You medical men have duties to perform in our hospital, and it is not enough that these are faithfully and honourably discharged. It is not enough that your forefathers have so raised the prestige of our hospital that we can, and do, insist on your having the highest qualifications, and practising as pure physicians, surgeons, and specialists—that you have suggested yourselves because it appeared a real advantage to the institution—but, notwithstanding this, we compel you, whether you like it or not, to accept terms which are vexatious, if not derogatory, by binding you to forego any other charitable effort, or to accept any remunerated office usually held by consultants. In your young years you may waste your spare time in any way you wish, but one thing you shall not do. You shall not, in your keen love of your profession, serve another hospital, to gain experience outside our walls, that you may become better physicians or surgeons. . . . We do not suppose for a moment that the generous and honourable laymen of our hospitals are capable of deliberately injuring or slighting their staff. It must surely be misconception only that induces them thus to forget what they owe to the medical profession, for medical science is undivided, and is not only national, it is international. If the medical work at British hospitals is to be honorary, let it be continued as the charity of the whole medical profession; otherwise, it should be treated on true business lines, and duty paid for like the buildings, food, and nursing. Let us wake up, and see that the laymen do not exploit the profession, and ruin our work with their so-called 'business principles.' The blow is none the less hurtful because it is dealt by friends."

St. Bartholomew's Hospital New Buildings.

THE site of this ancient institution has recently been extended by the purchase of one and a half acres of adjoining land from Christ's Hospital. The foundation-stone of the first new block of buildings was laid by His Majesty the King in 1904, and formally opened by H.R.H. the Prince of Wales, President of the Hospital, in July last, it being ready and in full working order at the opening of the winter session yesterday. The new buildings contain the following accommodation:—The club rooms of the students' union, residential quarters for the house physicians, house surgeons, and other members of the residential staff, and for the maternity clerks during their periods of duty. A separate dining room, with a smoking and a recreation room, are provided for the resident medical officers, and each has his own sitting-room and bedroom. All are conveniently arranged and furnished so as to afford accommodation for the resident staff second to none in the kingdom. Beside these there is a new casualty department, 140 feet long and 45 feet wide, which gives seating accommodation for 850 people; a new medical out-patient department, and a surgical out-patient department, an operation theatre, a dressing and sterilising rooms, etc., have also been added. There are also departments for diseases of women, ophthalmic, and aural cases, and for diseases of the throat and nose. Special accommodation has been also provided for orthopaedic, skin, X-ray, and electrical cases, whilst additional rooms have been set apart for the dental department, and a new clinical lecture theatre, and a new chemical laboratory complete these extensive and ideal premises.

St. Mary's Hospital Medical School, Paddington.

As the result of the examinations for the Entrance Scholarships, 1907, held on September 23rd, 24th, and 25th, the following awards have been made:—Open Scholarships in Natural Science: £145, J. T. S. Gibson, Aske's Haberdashers' School; £78 15s., C. R. Harrison, Balham School; £52 10s., W. B. James, Derby Municipal Technical School; £52 10s., C. E. S. Jackson, Haileybury College. University Scholarships: 60 guineas, H. B. Richmond, B.A., King's College, Cambridge. Exhibition of 30 guineas, P. N. Cave, B.A., University College, Oxford.

Medical Man's Struggle on a Liner.

DR. FRENCH, the surgeon on the White Star liner "Majestic," had an alarming experience during the voyage to New York last week, narrowly escaping from death at the hands of an insane stoker. On the third day out, one of the stokers came to him in his surgery. Dr. French had no reason to feel alarmed at the man's appearance, but was surprised when the latter turned and locked the door behind him. Then, without any warning, the stoker threw himself upon the doctor, hurled him to the floor, and fiercely attacked him. Dr. French was unable to resist the maniac's strength, and could only cry out for help. The stoker held him by the throat, and the unfortunate doctor was being rapidly strangled when one of the ship's officers, finding it impossible to effect a rescue by means of the door, fired a revolver through a grating and shot the lunatic. The man fell back badly wounded, and Dr. French hastily flinging open the door pinned the man to the ground until assistance arrived.

Sanitary Committee.—Notification of Births, Doctors' Objection.

THE General Purposes Committee reported that they considered the advisability of the adoption of the Notification of Births Act, 1907, and that the Town Clerk reported that the Act, which required adoption by the Council with the consent of the Local Government Board, required the father of a child, if residing in the house where it was born or any person in attendance upon the mother at the birth, or within six hours after, to notify the birth to the Medical Officer of Health for the district within 36 hours of the event, the notification being in addition to the ordinary registration of birth. The Act provided that a person should not be liable to the penalty prescribed for non-compliance if he had reasonable grounds to believe that some other person had given the notice, and that the notice might be given by post-cards, which were to be supplied, stamped and addressed by the local authority, free of charge to any medical man and midwife who applied for them.—It was resolved that the Council be recommended to take the necessary steps for adopting the Act.—Mr. Peacock moved the adoption of the report, and Mr. Tonkin seconded.—Dr. Preston King moved that the matter be referred back to the committee for further consideration in order that the opinion of the medical men of the city might be obtained. The adoption of the Act was only optional, and he thought the committee ought to refer it to the Bath branch of the British Medical Association. The Act placed upon the medical men, in the absence of the father, the necessity of notifying the birth, and thus rendered him liable for doing something for which he got not one penny or thanks of any sort. If the Government had simply reduced the time during which notification was required to be made, and retained the machinery of the old Act, which made the father responsible, it would have been all right.—Mr. Tonkin said the Act seemed to him to be a very sensible one. All that was required to be done was that postcards should be sent notifying the birth.—Alderman Vincent seconded Dr. Preston King's amendment.—Mr. Spear said the idea on the part of the committee was that the Act would be adopted. Dr. Symons reported the recommendation then, but now thought it would be better to withdraw it and refer it back on the ground that the medical men of the city objected to writing a postcard and sending it unless they were paid for it. He (Mr. Spear) was not in sympathy with the attitude of the medical profession.—Dr. Ryan said he would be very sorry to think that the medical profession in Bath as represented by Dr. Preston King would stand in the way of such an excellent measure, and he personally would be very sorry to accept anything for the trouble of writing a postcard of that sort. He hoped the matter would not be referred back.—Dr. Preston King said that those words, as coming from another medical man, were hardly justified. He was not speaking personally, but from what he could gather from one or two medical men who were also absolutely impersonal in the matter, because they were not affected by it. Before an Act which was optional was adopted, the persons who were going to be affected by it ought to have the chance of being consulted, and those in question would not have that chance if the Act was adopted that morning. It was not the question of a fee that was the main thing, but the fact that the Act would render medical men liable to a penalty if they did not do certain things. They had a right to be consulted.—Mr. Spear pointed out the duty of sending the card was not thrown upon the doctor primarily, but upon the father, and the doctor was not liable to a penalty if he had reasonable ground for believing that the notice was sent by someone else in the house. The Act had been passed as part of a great question—the question of infantile life in the country. He was glad to know that Dr. Ryan was thoroughly in favour of the proposals.—The Medical Officer said he did not think they should throw upon the medical men the necessity of sending the postcards. His own idea at the time the recommendation was passed by the committee was that it would not call upon the medical men at all. When the Act was before Parliament the idea was that the medical men should not be made liable, but owing to bad faith the clause was included. —Mr. Spear said that any prosecution would have to be first ordered by that committee. They would not be likely to see an injustice done a medical man of the city.—Dr. Preston King's amendment was lost by five votes to four, and the recommendation in favour of the adoption of the Act was then carried unanimously.

Prizes for Mothers.

THE town of Leipzig has resolved to give prizes to mothers who nurse their own babies for a certain length of time. The mothers applying for prizes are under the supervision of doctors, midwives, and certain female clerks of the town orphanage. Midwives who persuade mothers with success to nurse their own children are entitled to a money present.

The Sea Water Cure.

A TRAGICAL ending to an experiment with Dr. Quinton's sea water injection cure has just thrown an aristocratic family into mourning.

Count Victor Benedetti, grandson of the last Ambassador of the Empire at Berlin, and godson of Prince Napoleon and Princess Mathilde, was taking a rest from overwork at Fontainebleau with his father and mother. In spite of their remonstrances, being attracted by the wonderful accounts given of the success of Dr. Quinton's methods, he insisted on trying them. The most minute precautions were taken to obtain the freshest serum, and the operation of subcutaneous injection was performed.

The next day M. Benedetti complained of violent headache, and on the following morning high fever set in. The celebrated surgeon, Dr. Cuneo, was hastily summoned from Paris, and he hoped at first that it might be possible to localise the poisoning, but the strength of the patient was not equal to the vigorous treatment required, and he sank quickly.

It is not yet certain whether the materials used were defective, or whether the constitution of the patient was naturally refractory to a treatment which has certainly produced marvellous results on others, but the case proves that the new remedy is one that, for the present, at least, must be viewed with mistrust.

The Royal University of Ireland.

THE following candidates have passed the undermentioned examinations:—

The First Examination in Medicine.—Pass.—Samuel Acheson, Abraham N. Berman, Mary K. Carroll, Vincent A. Cox, Frederick Crooks, Cuppage Burke, Daniel J. Enright, Samuel R. Foster, George H. Hayes, Thomas Hill, Richard McCulloch, Harold McDonald, Thomas J. R. Maguire, Henry F. Moore, George R. Naylor, Louis J. Power, Joseph Prendivilte, Adiel E. H. Reid.

The following candidates may present themselves for the further examination for Honours in the subjects set after their respective names; those qualified in two or more subjects may present themselves for all:—Vincent A. Cox, Frederick Crooks, Daniel J. Enright, Samuel R. Foster, Thomas J. R. Maguire, Henry F. Moore.

The Second Examination in Medicine.—Upper Pass. —Richard H. Barter, Harold Black, Michael J. Fogarty, Thomas J. Kilbride, Patrick D. McCullen, Stephen A. McSwiney, Michael Moloney, Denis Murphy, Thomas Reynolds, Charles J. Simpson, James Stewart. All the above candidates may present themselves for the further examination for Honours.

Pass.—James T. Brady, Percy M. J. Brett, Francis J. Burke, Louis Cohen, George Cooper, Robert C. Cummins, Thomas A. Daly, Ernest S. Dixon, Herbert Emerson, Thomas Fitzgerald, Philip J. Gaffikin, George S. Glass, B.A., James J. Hanratty, Charles A. P. Harrison, Timothy F. Hegarty, Daniel Higgins, Robert A. Kerr, Alfred J. Moran, Joseph E. O'Sullivan, Gerard Sheridan, William J. Smyth, John Stephenson, Bernard Teeger, Francis J. Wisely.

Exempt from further examination in Practical Chemistry.—Jane L. Law, Mary A. Murphy.

Apothecaries' Hall of Ireland.

AT a meeting of the Court of Directors the following were elected Examiners for the ensuing year:—

Chemistry and Physics.—Prof. Hugh Ryan, D.Sc., F.R.U.I.; J. J. O'Sullivan, L.R.C.P.S., D.P.H. Biology.—Prof. D. J. Coffey, M.D., F.R.U.I.; John Knott, M.D. Anatomy.—Prof. Frazer, M.D., F.R.C.S.; P. J. Fagan, F.R.C.S. Physiology.—Prof. D. J. Coffey, M.D., F.R.U.I.; John Knott, M.D. Medical Jurisprudence.—W. Fottrell, L.R.C.P. and S.I.; J. C. McWalter, M.A., M.D., D.P.H. Pharmacy.—J. A. Walsh, L.R.C.P. and S.Edin.; J. C. McWalter, M.A., M.D., D.P.H.; E. F. Hanrahan, M.B., B.Ch. Materia Medica.—John Evans, L.R.C.S.I.; John D. Crinion, L.R.C.P. and S. Pathology.—J. L. Keegan, F.R.C.S.; R. J. Rowlette, M.D. Hygiene.—Sir C. Cameron, C.B., M.D.; C. J. Powell, F.R.C.S., D.P.H. Ophthalmic Surgery.—H. Mooney, F.R.C.S.; F. Odevaine, F.R.C.S. Medicine.—John Marshall Day, M.D., D.P.H.; John O'Donnell, M.B., B.Ch. Surgery (appointed by the General Medical Council).—Sir Lambert Ormsby, M.D., F.R.C.S.; Prof. Conway Dwyer, M.D., F.R.C.S. Midwifery and Gynæcology.—Gibbon Fitzgibbon, M.D.; R. J. Fleming, M.D.

University of Durham.

THE following candidates have passed the first examination for the degree of Bachelor in Medicine, September, 1907:—

1.—Elementary Anatomy and Biology, Chemistry and Physics.—Honours.—First Class.—John Hamilton Barclay, Michael Brennan. Honours—Second Class. —William Hudson. Pass List.—Joseph Jopling Brown, Eleanor Walkinshaw.

2.—Chemistry and Physics.—John Bain Alderson, Ronald Grieg Badenoch, Richard Murray Barrow, Roger Errington, David Farquharson, Sarah Louisa Green, Thomas Albert Hindmarsh, Laurence Heber Warneford Iredale, Frank Hutchinson Kennedy, John Lumb, Benjamin Bell Noble, Charles O'Hagan, Arthur Hyde Wear.

3.—Elementary Anatomy and Biology.—Louis Ernest Seïde Gellé, Harold Llewellyn James, Russell Vyoyan Steele.

The following candidates have pased the second examination for the degree of Bachelor in Medicine:—

Anatomy, Physiology, and Materia Medica (Pass List).—Oscar Frederick Don Airth, Isaac Bainbridge, Helen Grace Clark, Robert Vickers Clayton, Bloomfield George Henry Connolly, John Hare, Samuel Littlewood, George Cuthbert Mura M'Gonigle, John Howard Owen, Madeline Rosa Shearburn, Matilda Ann Sinclair, Eric Hemingway Shaw, Carl Johan Valfrid Swahnberg, Olivia Nyna Walker, Stanley Worthington, James Carruthers Young.

The following candidates have passed the third examination for the degree of Bachelor in Medicine:—

Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.—Honours—Second Class.—Robert Raffle. Pass List.—Hubert Cyril Willoughby Allott, Harriett Amelia Apps, Alexander Hay Bower, John George Campbell, B.A., Leslie Wilson Evans, Patrick Albert Galpin, Francis Frederick Hare, Edward Pierce Hughes, John Pritt Jackson, Annie Viccars Mack, Charles James Neilan, Ruth Nicholson, Charles Elias Reindorf, Theodore W. Stallybrass, Harold Widdrington Sykes, Dorothea Mary Tudor.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

THE INVENTION OF SPECTACLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent on this subject in the last issue (September 25th) is in error in supposing that the quotation "Now we see through a glass," etc., might be translated "through glasses." The Greek word means a "mirror."

Yours faithfully,

HEYWOOD SMITH.

25 Welbeck Street, Cavendish Square, W.,
September 26th, 1907.

M. O. H.—As with most questions, there are two sides to the health visitor matter. In his last report, the medical officer of health for Hammersmith says: "It is interesting to note that, notwithstanding the fact that the council appointed a lady health visitor, with the object of lessening the infantile mortality, it has actually gone up eleven per 1,000 as compared with London. These facts rather tend to prove that the causes of infantile mortality are, to a very considerable extent, due to social conditions, and are beyond the power of sanitary authorities to prevent. I am not of opinion that any practical good is achieved by the appointment of lady health visitors." We are inclined to think that such an opinion is not that generally held.

SCHOOL HYGIENIST.—The French have a much more thorough procedure for the prevention of infectious diseases through school influence than anything we know of here. In a recent edict from the Minister of Public Instruction to public elementary school authorities, the most stringent precautions are specifically enjoined. For instance, in the case of scarlet fever, not only is the child to be excluded from school, but his books are all to be destroyed, and general disinfection of the school carried out. Similar precautions are enjoined in the case of measles, and all pupils under six may be excluded from school as well. With regard to small-pox, re-vaccination of all teachers and children is required, in addition to all other measures.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 2nd.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.; Mr. J. Berry: Clinique. (Surgical.)

THURSDAY, OCTOBER 3rd.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wale's General Hospital, Tottenham, N.).—4 p.m.: Opening Lecture:—Dr. W. H. White: The Various Conditions causing Enlargement of the Liver. (In conjunction with the North-East London Clinical Society.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: The Present Position of Dermatology.

FRIDAY, OCTOBER 4th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. A. Lawson: Clinique. (Eye.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. W. Edmunds). Clinique:—Ophthalmological (Mr. Brooks). 3 p.m.: Clinique: Medical In-patient (Dr. M. Leslie).

Appointments.

DAY, W. F. L., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.Lond., Medical Officer and Public Vaccinator for the Parndon, Nazeing, and Roydon Districts of the Epping Union.

EVANS, R. E., M.D., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Newcastleton District of the county of Roxburgh.

HILTON, ALBERT, L.S.A., Medical Officer of Health to the Hurst District Council, Ashton-under-Lyne.

KING, D. BARTY, M.D., M.R.C.P.Edin., Examiner in Medicine and Clinical Medicine at the University of St. Andrews.

MARCH, GEOFFREY COLLEY, L.R.C.P.Lond., M.R.C.S., District Medical Officer by the Dorchester (Dorset) Board of Guardians.

RIGGALL, ROBERT MARMADUKE, L.R.C.P., Third Assistant Medical Officer to the Devon County Asylum, Exminster.

TURNOR, P.W., L.R.C.P., M.R.C.S.Eng., Certifying Surgeon under the Factory and Workshop Act for the Penkridge District of the county of Stafford.

VAN BUREN, ASA CLAUDE ALI, M.D., B.S.Lond., L.R.C.P., M.R.C.S., Honorary Anæsthetist to the Torbay Hospital, Torquay.

Vacancies.

Riccartsbar Asylum, Paisley.—Resident Medical Officer. Salary, £120 per annum, with board and apartments. Applications to J. M. Campbell, Clerk, Parish Council Buildings, Paisley.

Manchester, University of.—Senior Demonstrator in Physiology. Salary, £150 per annum. Applications to the Registrar.

Manchester Royal Infirmary.—Resident Surgical Officer. Salary, £150 per annum, with board and residence. Applications to Walter G. Carnt, General Superintendent and Secretary, Manchester Royal Infirmary.

Jersey Dispensary.—Resident Medical Officer. Salary, £120 per annum, with furnished quarters and attendance. Applications to Secretary.

Bradford Poor-Law Union.—Resident Assistant Medical Officer. Salary, £100 per annum, with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians, Union Offices, 22, Manor Row, Bradford.

Brompton Hospital Sanatorium.—Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications to the Secretary, Brompton Hospital, London.

Worcester County and City Asylum.—Third Assistant Medical Officer. Salary, £140 per annum, and all found. Applications to Superintendent, Powick, Worcester.

Three Counties (Gloucester, Somerset, and Wilts) Sanatorium for Consumptives, Winsley, near Bath.—Resident Medical Officer. Salary, £200 per annum. Applications to the Secretary.

Provincial Hospital, Port Elizabeth.—Assistant House Surgeon. Salary, £225 per annum, with board and residence. Applications to H. Chaplin and Co., 9 Fenchurch Street, London, E.C.

Hull City and County Lunatic Asylum.—Second Assistant Medical Officer. Salary, £150 per annum, with board, apartments, washing, and attendance. Applications to the Chairman of the Asylum Committee, care of the Town Clerk, Town Hall, Hull.

Lewes Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer. Salary, £120 per annum, furnished apartments, board, coal, gas, washing, and attendance. Applications to Secretary.

Births.

DUNN.—On Sept. 23rd, at Murree, Punjaub, India, the wife of Major H. N. Dunn, R.A.M.C., of a son.

HILL.—On Sept. 25th, at Raincliffe, Dorset Road, Bexhill-on-Sea, the wife of Walter de Marchot Hill, M.R.C.S., of a daughter.

Marriages.

COATES—EWER.—On Sept. 24th, at the Cathedral, Capetown, South Africa, John Coates, F.R.C.S., second son of Edward Coates, of Fulham, London, and Heacham, Norfolk, to Winifred Julia, only daughter of William Thomas Ewer, of Prince's Avenue, Muswell Hill, London.

CUNNINGHAM—WINZER.—On Sept. 27th, at St. John's Church, Westminster, Robert Allan Cunningham, Captain R.A.M.C., second son of R. A. Cunningham, Esq., of Ballybofey, Co. Donegal, to Hope Caroline, youngest daughter of the late J. E. Winzer, Esq., of Hamburg.

DENNIS—RUCK.—On Sept. 25th, at St. Ambrose Church, Bournemouth, Albert Lewis, youngest son of the late Rev. G. M. Dennis, of West Meath, Ireland, to Constance Anne, youngest daughter of the late David Ruck, Esq., M.R.C.S., of Cirencester, Glos.

SEARS—DEW.—On Sept. 28th, at Sydenham Baptist Church, Forest Hill, Charles Newton Sears, M.D., B.S.Lond., M.R.C.S., L.R.C.P., of "Point View," Burnt Ash Hill, Lee, second son of J. Tresidder Sears, Esq., J.P., of Lee, to Annie Florence, the youngest daughter of Charles Dew, Esq., of Forest Hill, London.

Deaths.

JENKINS.—On Sept. 26th, at Colomendy, Ruthin, Josiah Roberts Jenkins, M.D., J.P., in his 81st year.

MEAKIN.—On Sept. 21st, at Nordrach-upon-Mendip, Captain Harold Budgett Meakin, M.D. (Indian Medical Service), aged 37.

STEWART.—On Sept. 27th, Professor Charles Stewart, LL.D., F.R.S., of 38 Lincoln's Inn Fields, Conservator of the Museum of the Royal College of Surgeons of England, aged 67.

WHITE.—On Sept. 2nd, at Hampstead, Major R. W. Persse White, Welsh Regiment, son of the late Robert Persse White, F.R.C.S.I., Dublin.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, OCT. 9, 1907. No. 15

NOTES AND COMMENTS.

Radium for Everything.

THE quack dealers have not hitherto displayed their wonted enterprise in the exploitation of radium as a cure. Considering how electricity and other kindred discoveries have in the past enriched unscrupulous scoundrels who advertised them as cure-alls, and considering also how much more activity there is in the quack world now-a-days, one cannot help wondering whether the enormous price of radium or whether its feeble therapeutic power has been the drawback. As to the price, that need not, on the electric-belt theory, be a consideration at all, for it would not matter whether radium was present or not so long as the advertisements and the testimonial writers said that it was; and as to therapeutic powers the mere fact that doctors had found it of little service would have been the best card a quack-merchant could play to show the unique character of his "discovery." Nevertheless, we have waited in vain. Last week, however, "The Radite Company" ventured into the field and issued a leaflet describing the virtues of their "radite powder," composed mainly of pitchblende and radite, and containing radium. This wonderful powder brings radium into the therapeutic field of the million, and it should be purchased, say the company, by all persons suffering from pain of any kind, all persons suffering from eczema, psoriasis, acne, and other skin diseases, and persons whose hair is growing thin, and so on.

"Freckles and Other Morbid Growths."

THE powder is to be applied in various ways, either on a pad, or as "radite water," or as a "radium disc," which latter will remove warts, corns, moles, birthmarks, freckles, and other morbid growths (*sic*). Malign surface tumours, rodent ulcers, cancer of the skin, and sores in general, may be greatly ameliorated, and in many cases cured by the application of a radium disc. Such a disc is supplied in leather cases for 7s. 6d., whilst "radite powder" costs 5s. per ounce. Now, as radium bromide itself costs £453,592 per ounce, according to the statement of the company, it would make a pretty calculation to ascertain how much radium is contained in radite powder, but perhaps this poverty in the element should really be regarded as the safeguard of this preparation, in that there is not much likelihood of radium-burns. In order that "radite" may become better known a competition on the lines of the present Limerick craze is being organised, and whether the competition or the remedy is to prove the more popular remains to be seen. Still, now the ice is broken we shall probably soon have as many quack advertisements of radium preparations as there lately were of electric belts and batteries, and all of about equal therapeutic efficacy.

Australia and Quack Medicines.

WITH regard to quack medicines, last Christmas the Government of Australia appointed a Royal Commissioner, not a medical man, to inquire into the question of quack medicines in the Commonwealth, and to recommend what steps should be taken with regard to them. This gentlemen, Mr. Beale, has recently issued his report, which is a very voluminous one, and the conclusions he comes to are most far-reaching and important. He recommends that letters-patent should be issued for approved and novel formulæ for the prevention and cure of human ailments, and though this suggestion would sweep away all present patent medicines, not one of which is novel or original in any degree, we fear it would tend to act as a commercial incentive to real discoverers who now give their work freely to the world. Still, such a rule would do no harm if it were more honoured in the breach than in the observance, except in so far as concerns the denying of patents to remedies that are not novel, and such refusal in itself would constitute a valuable reform.

And Their Cure.

BUT Mr. Beale's further recommendations are those which lie at the root of all proper patent medicine regulation. He suggests that every patent medicine when retailed shall bear its formula of preparation on a label; that no advertisement shall be allowed on the article itself or its covering; that no advertisement of any proprietary or secret cure shall be allowed to be published; and that transmission of advertising matter concerning such medicines through the post shall be forbidden. If we make the slight reservation that genuine new preparations prepared by respectable firms should of course be made known to medical men through the post and by advertisement, we can most cordially endorse Mr. Beale's conclusions, which would finally dispose of the most glaring public fraud of the day. It is a humiliating but none the less a well-deserved reproach that this Colonial Commissioner should point to the Mother Country as demanding "an eighth share in the full retail price of every, even the most pernicious, proprietary specific under quasi-medical pretence." We recently drew attention to the interesting fact that the Cape Legislature recognised the undesirable character of certain cancer "remedies," and forbade their sale; New Zealand is making a big struggle against the newspaper interest to rid herself of the plague; and Australia has its way now mapped out for it, if it will move. The "Old Country" has not even turned in its bed.

Temperance Research. WE have been asked to notice the proposals of the Education Committee of the National Temperance League with regard to some operations they hope to take in hand. This committee is asking for funds to promote scientific research into the nature and effects of alcohol, to translate scientific treaties on the same subject from Continental language into English, to distribute literature dealing with the effect of alcohol on the human organism to leaders of thought, to hold education conferences, to promote the teaching of hygiene and temperance in schools, and to publish fresh evidence as obtained regarding the deleterious action of alcohol on the tissues. These are highly commendable objects, and the committee is strongly manned with names which command respect, but we cannot help thinking that the League, being a militant one, would do well to leave research alone. Scientific inquiries are best conducted in an absolutely impartial atmosphere; indeed, we might say, can only be so conducted. The temptation of making facts square with predilections is so great to our frail human minds that any research work conducted by the League would necessarily fall under the suspicion of being biassed, and surely there must be plenty of educative work to be done on facts already known.

LEADING ARTICLE.

THE SHEFFIELD UNION INFIRMARY DEADLOCK.

THE touch of sensationalism given by the lay Press in their headlines, "Doctors on Strike," in connection with the recent occurrences at the Sheffield Union Infirmary, was in no way justified. There has been no "strike." The rules and regulations under which the staff worked did not conduce to comfort and pleasure on the part of the resident staff; dissatisfied with their position, they resigned, as they had a perfect right to do, and there had been several resignations during the preceding year. The Guardians wished to have a visiting staff, consisting of a physician and a surgeon, whose position was to be more or less honorary, but who were to receive an honorarium or salary for their services, fixed respectively at £141 15s. and £115 10s. a year. They were fortunate in securing the services of two of the leading men in the town to take the positions, chiefly because of the increased clinical experience attached thereto. No one could say that the remuneration erred on the side of full market value, when it is remembered that they were responsible for the treatment of all the patients in a hospital of 500 beds, and that they were bound to visit three times a week, the rate of pay being less than £1 a visit. To assist them, three resident medical officers were appointed, their positions being on a par with that of house surgeons in an ordinary hospital. The main source of difficulty arose in trying to meet the requirements of the Local Government Board, as to having a responsible officer to discharge the duties of "Medical Superintendent." Neither of the visiting staff accepted that position. It was sought to place the burden upon the senior resident medical officer. Whilst asking him to take on these duties, the Guardians refused to define the limitations of his duties and responsibilities. The resignations which have taken place from time to time arose from the friction to which this unsatisfactory condition of affairs not unnaturally gave rise. The residents say that the Guardians treated them with a want of proper consideration when they brought matters to their notice; the Guardians seem to have thought that all that these young men had to do was to receive any orders that were given to them, and carry them out without any reference to what their feelings in the matter might be. It is hardly surprising that this scheme of the Guardians was found in practice not to work, however estimable it might have been in theory. The absence of a well-paid, responsible officer at the head of affairs, whose duty would be to see that the requirements of the Local Government Board were properly carried out, who, on the one hand, would have the affairs of the hospital, as to staff and management, well under control, and on the other, would be responsible to the Board for the administration of the institution, is the real cause of the recent breakdown of the Guardians' scheme, and of the resignations which have taken place. The cost of the recent scheme was £557 5s.; when one remembers that there are 500 beds in the hospital, no one can say that the Guardians rate the services of their medical men too highly. The old order having passed away, the new scheme of the Guardians is as follows: There are three resident men to be appointed; a superintendent medical officer, who is to be between thirty and forty years of age, and who is to have a salary of £300 a year, with board and residence, and two assistant medical officers, with salaries of £100 and £80 respectively, the total cost to be £480. The change effects a saving of some £75 5s. Three men are to do the work of the five that held the appointment before. The writer of "Current Topics" in the *Sheffield Daily Telegraph* says, "We should like to know how it comes about that if three doctors are sufficient now, five were employed heretofore. In other words, can three men do five men's work? The saving, of course, is fatuous; the figure is too small to worry about. It is only efficiency that matters in such a case." Of course, if men are to be fouud who are satisfied with such remuneration for so responsible a post as that of medical superintendent, having reached the age of between 30 and 40, there is no more to be said; the Guardians would be foolish to pay more. Possibly the class of cases admitted to such infirmaries may not be such as to require a high order of medical knowledge or skill, and there are men whose ambition in life would be quite satisfied, at such an age, with the benefits and emoluments of such a post. They are not likely to go much farther in the race of life. We can but wait and see how matters work out.

The Guardians tried to throw the responsibilities of the resignations upon the Sheffield District of the B.M.A. They said it was the result of action taken by the District. This, of course, the local secretary was able at once to repudiate. The District had taken no action in the matter until after the resignation of the three residents. They then considered matters, and came to the conclusion that it was not their concern; but, contrary to the wishes of several men in the District, they passed a resolution, that "they considered, under the circumstances, that the posts at the Infirmary were untenable." Those who objected to their taking any notice of the affair at all did so on the grounds that, as they were not going to meet a delegation from the Board of Guardians to discuss matters, or mix themselves up in the affair, it would be wiser to say nothing, as any action of theirs would only be taken on a one-sided statement of what had taken place.

THIRD REPORT OF THE ROYAL COMMISSION ON VIVISECTION.

The Royal Commission on Vivisection has just issued the third volume of the minutes of evidence taken before it, and without prejudice it may be said to be even more damning to the "cause" than its predecessors, little encouraging as they were. An interesting witness was Lord Justice Moulton, who, as an eminent lawyer and a scientific man having had no personal contact with experiments on animals, may be regarded as what he was actually called by Lord Selby "a highly qualified outsider." Lord Justice Moulton, both from the point of view of the increase of knowledge and from that of ethics, was in favour of the practice of experiments on animals under due regulation, holding that one is justified in the present state of affairs in inflicting a lesser evil when there is a reasonable prospect of avoiding a very much greater one. But from the logical moderation of Lord Justice Moulton we turn to the utterances of the Hon. Stephen Coleridge, who was under examination for three days, and who managed in that time to execute a series of verbal gymnastics which may well puzzle both his satellites and the objects of his venom. Since the days of the Bayliss libel trial, when Mr. Coleridge was convicted by twelve of his fellow countrymen of the sin of "talking through his hat," there have at times been signs almost of grace in that eminent protagonist, but we confess that we raised our eyebrows when we read that Mr. Coleridge, in his evidence, said that he directed himself against the infliction of suffering, but did not object to the utilisation of animals for scientific purposes, provided it was painlessly conducted. We must not too hastily assume that Mr. Coleridge is now a moderate vivisectionist, as these words would seem to imply, for it seems he considers anæsthesia, when testified to by expert physiologists, as not sufficient for his purposes. Apparently he considers scientific men as ready to state any untruth to cover their misdeeds. Experimenters, he said, would deny a breach of the Experiments on Animals Act, 1876, just as he himself would deny a breach of the Motor Car Act. "I drive a motor car, and when I go beyond the speed limit and a policeman asks me, I say, 'No, I am not going beyond the speed limit.' Nothing would keep me from going beyond the speed limit except the presence of a policeman in the car." On being asked whether he would expect his word to be disbelieved, Mr. Coleridge replied, "No, I do not say so." If anyone can make rhyme, reason, sense, or consistency out of Mr. Coleridge's efforts before the Commissioners, they will have accomplished a task beyond the powers of plain men who are accustomed to use the word "Yea" and "Nay" in their exact and literal signification. Miss Lind-af-Hageby, of "Shambles of Science" fame, gave evidence to the effect that she did not believe that vivisection experiments were generally carried on under deep surgical anæsthesia—and against a woman's belief it would be absurd to argue—and also that she objected to vivisection on the whole principle of exploiting the lower animals for our supposed service and use. The latter is a comprehensible position, but if adhered to by a society which eats beef and eggs, drinks cows' milk, drives in 'buses (not motor), and wears boots, it would entail considerable change in custom. Beyond these witnesses there were some minor anti-vivisection lights, and a number of scientific and medical men, but their evidence pales into insignificance before that tendered by Mr. Coleridge and Miss Hageby.

CURRENT TOPICS.

The No Man's Ground of the Milkman.

The community has much to endure at the hands of the milkman. Not least of all is the crashing of his pails and the rattling of his springless carts. When the small things of social reform come to be handled by county councils we may hope to have springs fixed to his—and for that matter to all tradesmen's—barrows, and buffers attached to milk cans, so as to lessen their brazen and altogether unnecessary clatter. So much for milkman's form, now for his material. On the whole there can be little reasonable doubt that an immense amount of diluted milk is daily palmed off upon a long-suffering public. In spite of laws and by-laws galore the merry milkman, with a mild twinkle in his meditative eye, goes his way from morn to eve placidly retailing water at the price of pure cow's milk. Truth to say, legislation, whether of Parliament or of local council chamber, has left him on a sort of Tom Tiddler's ground, whence he may survey with indifference the heathen raging of the sanitary authorities. If he is haled into court all he has to do is to produce a warranty of purity from the farmer who has sold him the milk, and to swear he has retailed it in the same condition. He promptly leaves the court without a stain upon his character. The farmer never attends, and the difficulties in the way of fixing the offence upon the farmer are hopeless. The way out of the wood—as recently pointed out by the correspondent of a London daily—is to summons both milk dealer and farmer together, and let them fight it out in court. Then there would be some chance of the honest ratepayer coming by his own.

The Veterinary College and Unqualified Practice.

The College of Veterinary Surgeons, fortunately for its diplomates, seems prepared to protect their rights in a way that might well be taken to heart by our own Medical Colleges. At Feltham Petty Sessions the Veterinary College prosecuted an Ashford resident, named Wilson, for stating that he was specially qualified to practice a branch of veterinary surgery by publishing the description "canine and feline medical expert." The owner of a St. Bernard puppy stated that he took the dog to defendant, who produced a stethoscope, and having examined the dog all over, said it suffered from kidney disease. £1 was paid, and the dog left with defendant, who wrote saying the animal was suffering from rickets, and later, again, from worms. The dog was with him from April 15th to June 13th, and 12s. 6d. was paid weekly. The defendant stated he had practised for seven years in Ashford as a canine and feline medical expert. He had never claimed to belong to the Royal College of Veterinary Surgeons. Had he omitted the word medical from his description dogs and cats would have been brought to him for an opinion as to their value only. The Bench convicted defendant, and imposed a fine of 20s., including costs. It would be of interest to know in how many instances, say, during the past twenty years, prosecutions for illegal practice have been undertaken by the Royal Colleges of Surgeons of the United Kingdom. Their attitude in this respect, indeed, to some extent, warrants the inference that having taken the qualification fees of their diplomate their interest in his welfare ceases. In any case it is abundantly clear that our own Royal Colleges have neglected the duty that should be encumbent upon them of protecting their fellows, members and licentiates against the inroads of unqualified practice. It is no excuse for these ancient and wealthy corporations to plead that their statutory powers are insufficient. A little well-directed importunity would doubtless long ago have secured the necessary legislation. What the much-abused general practitioner wants is a one portal qualification with stringent laws against unqualified practice.

Deficient Mortuary Accommodation.

The inadequate mortuary accommodation in many parts of the United Kingdom, both rural and urban, has been the cause of public protest time out of mind. In certain districts, indeed, it has drifted into the position of a recurrent scandal. One of the worst features of the lack of proper accommodation is that dead bodies are often taken to public houses, where they lie in an outhouse until the inquest is held in the convenient taproom adjoining. As a rule, after a few strong protests, the matter is allowed to drop, and the same dismal tragedy is enacted again and again. Were all coroners as strong and determined as Dr. Drage, the Coroner at New Barnet, it is likely that before long the general public mortuary accommodation of the country would be considerably increased. At a recent inquest, being informed that a body had been placed in a stable infested with rats, he declared it was the duty of the overseer to provide a place for the reception of bodies. He then directed his officer, pending the provision of proper accommodation, to take bodies to the drawing-room of the nearest overseer. This order naturally brought the overseer up in arms. First, he provided temporary accommodation, and then cancelled his order, whereupon the Coroner's officer declared he would take the next body to the overseer's house, where, if refused admission, he would leave it on the doorstep. We understand that Scotland Yard has been summoned to the spot. Meanwhile, further developments may be awaited with interest.

Poisons in Sweetmeats.

It is, of course, a law of the land that certain poisonous drugs may not be sold to the public, except by registered chemists. The reasons for such limitation are obvious, and it is of importance to the safety of the public that the law in this matter should be strictly obeyed. By many methods, however, it is systematically evaded, and to one of these Sir James Crichton-Browne has drawn attention in a recent address. He has had analyses made of lozenges of various kinds commonly sold by grocers, and it has been found that such poisonous drugs as chloroform and chlorodyne are constituents of many of them. These noxious bodies are commonly combined with such innocent drugs as liquorice and linseed, and the compound is sold ostensibly to relieve cough. Sir James has evidence, however, that the lozenges are widely consumed as mere dainties, and there is little doubt that they are used for their analgesic properties. Analysis of certain lozenges sold in Liverpool showed from 2 to 3 per cent. of chloroform present. These lozenges were on sale in small confectionery shops, and could be bought without difficulty in any quantity. In other cases, lozenges containing chlorodyne were obtained with equal ease. There would seem to be no practical difficulty in the way of checking this noxious trade, now that public attention has been drawn to it. It is comforting to reflect, however, that so-called "chlorodyne" lozenges often contain no vestige whatever of the drug in question. A cheap substitute is used by proprietary nostrum vendors, in accordance with the universal rule among that fraternity, which hates expensive ingredients as the Devil is reputed to hate Holy Water.

The Police and the Medical Profession.

Nowadays a great deal is heard about the high-handedness of police methods, and there seems to be in many cases a certain amount of justification for the charge. While making full allowance for the difficulties of a position which, on the whole, is filled with credit and honesty, it is nevertheless necessary to remind the force at times that they are the servants and not the masters of the public. The recent absolutely indefensible action of the police in their prosecution of Dr. Bagley, of Manchester, for obstructing and assaulting the police in the execution of their duty, affords an extraordinary picture of what an arrogant police official can do in defence of his own illegal act. Dr. Bagley was called in to an old man who had attempted suicide, and whose throat he stitched up. He remonstrated when the police wished to remove the old man to Ancoats Hospital, and joined the sons in an ineffectual resistance to that removal. The magistrates held that the police had no right to enter the house and remove the man without a warrant, and they dismissed the case against Dr. Bagley. The latter, however, incurred costs to the extent of £30, which the Watch Committee refused to pay. The local medical profession have sent a strongly worded remonstrance to the Manchester authorities. It certainly seems hard that it should cost a private citizen £30 to teach the police an elementary lesson in their rights as regards apprehending an Englishman in his own house. After this occurrence possibly the Watch Committee will consider the advisability of classes of instruction and test examinations for its police constables.

The Midwives' Act.

The Midwives' Act has now been before the public and the medical profession long enough to justify comment upon its results. On the whole it may be said that while, on the one hand, there is no tangible evidence that the maternity of the kingdom is now being conducted under more favourable conditions, there is, on the other hand, considerable reason to believe that the forebodings of the medical profession are being more or less fulfilled. The general practitioner has to some extent ceased to devote himself to the serious practice of midwifery, a branch of work which was formerly one of the mainstays of the professional income. Moreover, it should be remembered that all knowledge in midwifery, on which the midwife depends for guidance, has been founded on the accumulated experience of many centuries of medical practice. The exercise of this most arduous craft has been handed over to a partially-educated class of women, the most crucial part of whose technical education consists in acquiring an inkling of the complications that need the highest of all possible professional endowments by way of skill, knowledge, and power to act. Has the average mother gained by the institution of that hybrid, the licensed midwife? We think not, for while a cold water douche has been thrown upon her old and faithful friend, the family doctor, she has been provided with a substitute who is admittedly unequal to face the unexpected, which in midwifery is often the difference between life and death. Now the midwife shares with the medical man the honorary privilege of notifying births, a logical extension of her rights that must fill with pleasure her drawing-room friends.

The Strait Jacket in the Workhouse.

A recent inquest held by Mr. Walter Schroeder on a patient who died at the Hampstead Workhouse Infirmary reveals a state of affairs that appears to demand full official inquiry. It seems that a man was sent to the institution named at 2 p.m. on Wednesday last, and died at 7.35 next morning, without having been seen by a medical man. About 11 o'clock on the night of his admission he became noisy, and the lunatic attendant, on his own authority, placed him in a strait jacket; he collapsed at 6.40 a.m. The medical attendant was telephoned for at 7 a.m, but the patient died before his arrival. This appears to be one of the recurrent workhouse scandals of a familiar type in which a delirious patient, a non-resident medical officer, a strait jacket and an overworked single-handed attendant play the chief part. It is to be hoped the Local Government Board will, in this instance, intervene so effectually that the possibility of a repetition of anything of the kind may be rendered impossible. At certain London institutions we believe something of the same kind has been going on for year after year. Where are the Medical Inspectors of the Local Government Board? Surely they were familiar with the shortcomings of the Hampstead Workhouse Infirmary organisation.

The Workmen's Compensation Act Referees as Witnesses.

Now that the medical referees have begun work in the Courts under the Workmen's Compensation Act it is desirable to consider the circumstances under which their office is discharged. Not long ago in the Liverpool County Court a point of vital importance was raised by counsel. It appeared that the medical referee had agreed to give evidence on behalf of defendant. His position was commented upon by the appellants in the severest terms. Quite reasonably, as it will appear to most plain men, they held that the referee, having accepted a judicial position, was by implication cut off from acting as a partisan expert. Counsel submitted that to adopt the latter function was indecent, and contrary to public policy, and that it was a difficulty provided against in the Act. The other side maintained that the referee was not bound to the county court in any official capacity, and his official appointment began only when he was appointed to any particular case. The judge held the same view, and ruled it was competent for the referee to appear as witness; but in such a case he would be invalidated from acting subsequently as referee to the Court. As a matter of good taste it would seem desirable that medical referees, except under most exceptional circumstances, should refrain from appearing as expert witnesses in compensation claims.

PERSONAL.

Dr. John Freeman, of University College, Oxford, has been elected to the Radcliffe Travelling Fellowship for this year.

We regret to record the death of Dr. Seneca D. Powell, Professor of Surgery in the New York Post-Graduate School and Hospital.

Sir Felix Semon will give a lecture to the Manchester Medical Society on October 16th on "English and German Medical Education—A Parallel."

Dr. George Reid will read a paper to the Incorporated Society of Medical Officers of Health on October 11th, at 5 p.m., on "The Planning of Schools."

Dr. Montague Murray will open the course of post-graduate demonstrations at Charing Cross Hospital with a lecture on "Medicine," to-morrow (Thursday).

Dr. J. Kingston Fowler, President of the Medical Society, will give his introductory lecture on October 14th at the inauguration of the 135th Session of the Society.

The Watch Committee of the Bradford Corporation have chosen for the chief police surgeonship William Wrangham, M.D. The appointment is for twelve months.

Canon Arnott, who was once Lecturer in Pathology at St. Thomas's Hospital, is to preach before the Society of Apothecaries at St. Andrews-by-the-Wardrobe.

Sir Lauder Brunton, M.D., LL.D., will deliver the inaugural address of the winter session at the London School of Tropical Medicine, Connaught Road, Albert Dock, on Monday, October 21st.

Sir Thomas Barlow, President of the Section, will give the opening address of the Clinical Section of the Royal Society of Medicine at 20, Hanover Square, on Friday, October 11th, at 8.30 p.m

Dr. James Collier opened the winter session of the National Hospital for Paralysed and Epileptic, Queen Square, London, yesterday (Tuesday) with a lecture on "Local Lesions of the Spinal Cord."

Professor Osler, F.R.S., will give the opening address at the University College Medical Society on October 16th on "The Influence of Medical Society on the Education of the Medical Student." Sir Thomas Barlow will be in the chair.

A CLINICAL LECTURE

ON

THE SPHYGMOMANOMETER IN MEDICINE.

By ROBERT SAUNDBY, M.D.Edin., Hon. LL.D., Hon. M.Sc., F.R.C.P.Lond.,

Professor of Medicine in the University, and Senior Physician to the General Hospital, Birmingham.

THE old authors described the pulse as large or small, hard or soft, quick or slow, and so late as the reign of Charles II. Sir John Floyer, of Lichfield, was the first who began to count it by its number of beats per minute, for which purpose he invented a special watch. From the time of Sir John Floyer the old terms "quick" and "slow" have been replaced by numbers and recorded in figures, so that in this respect at least every medical practitioner, thanks to him, thinks accurately and precisely. But for nearly two hundred years the other features of the pulse remained undetermined. In the sixth decade of the last century the sphygmograph of Marey placed in the hands of the clinician an instrument which enabled him to record upon paper the oscillations of the pulse, and to compare the curve of the hard pulse of Bright's disease with that of the soft pulse of pneumonia, and to study the changes produced by alterations of the valves of the heart the stethoscopic signs of which had recently been brought to perfection. The sphygmograph of Marey, excellent instrument though it was in the hands of patient and skilful observers, has been superseded by the simpler and more easily applied form introduced by Dudgeon, which has remained practically unmodified for twenty years—a striking test to the sound principles of its construction. A careful study of pulse tracings and a comparison of their curves shows that the amount of information to be derived from them has limits, and that contrary to what had been thought by the earlier observers it is impossible to rely upon them for estimating the blood pressure. The blunt-headed tracing often met with in high pressure pulses is due, not directly to the pressure, but to the prolongation of the systolic wave, which may proceed from other causes, and the pressure-gauge attached to the sphygmograph is conditioned by too many factors, such as the thickness of the tissues surrounding the radial artery, the rigidity of the instrument, and the tolerance of the patient, for the results to be relied upon. Various sphygmometers have been invented to supply this defect, such as the capsule of Prof. von Basch, which was constructed on the principle of an aneroid barometer, or Oliver's pulsometer, in which the force of the circulation is measured by the compression of a spiral spring. My experience of these instruments is that their readings are too variable in the hands of different observers to be of value. It was, therefore, a distinct advance when Barnard and Hill introduced an instrument consisting of a mercurial manometer, which measures in millimetres the pressure required to obliterate the pulse at the wrist. At the present time the sphygmomanometer of Riva-Rocci, as modified by Dr. C. J. Martin, is probably the best instrument available for clinical work; by it, in the course of two or three minutes, the pressure in the radial artery can be read off in millimetres of mercury. The pulse should be counted and recorded at the same time and observations which are intended to be compared should be made in the same position, either sitting or lying down, and the manometer should stand at the same level as the patient's heart. I have been using Dr. Martin's instrument daily for the last year, and have accumulated sufficient data to enable me to say something of the practical help it may give us.

In the course of this lecture it is not my intention to discuss the pulse pressure in all diseases, even if I had sufficient material from which to draw conclusions, but I propose to direct attention to some general facts and to the results of observations in certain forms of disease.

THE NORMAL PRESSURE.

From my own observations with this instrument the normal arterial pressure in healthy young adults has usually been between 125 and 140 mm. Hg.

AGE.

It is generally asserted that advancing age is in itself a cause of raised blood pressure, and so far as my observation goes this seems to be true, that is to say, people over 70, even when in perfectly good health and with no signs of arterio-sclerosis in the shape of thickened radial artery, have a blood pressure of about 170. Healthy middle-aged or elderly persons do not show any rise. Children on the other hand do not necessarily have a low pressure, and often are above the normal without any obvious cause. In fact, if my limited observations are to justify any conclusion it is that in infants and quite young children the blood pressure is more often from 140 and 150 than below, although where there is serious illness it may fall lower than it does in adults, as for instance in a child aged two years and four months, with broncho-pneumonia and fluid in the left side of the chest, the blood pressure was only 70 and pulse 160. Among adults low blood pressure (below 100) is very uncommon even where the patient is very ill. Thus I have recorded a blood pressure of 98 in a boy aged 14 with malignant endocarditis, and 95 in a boy of 13 with pericarditis; a girl of 14, suffering from phthisis, had a pulse of 120 and a blood pressure of 95 to 100. A man aged 34, with malignant endocarditis, had a blood pressure of 125, and a man aged 48, with fatal pericarditis, had a blood pressure of 185! I have seen the blood pressure as low as 95 in a married lady aged 43 with atonic dyspepsia, but it is in my experience quite an exceptional case.

ALCOHOL.

The influence of alcohol on the blood pressure was not quite what I had anticipated. The effect of half an ounce of whisky on a young man aged 28, in good health, is shown in the following table:—

Time.	Blood Pressure.	Pulse.
12.13	150	68
Half an ounce of whisky with soda water.		
12.25	135	64
12.37	170	60
12.52	130	56

In the case of a man with general dropsy from subacute nephritis supervening upon chronic Bright's disease, who had been ill two months, but had previously been very temperate in regard to alcohol and tobacco:—

Time.	Blood Pressure.	Pulse.
5.35	205	72
Half an ounce of whisky with soda water.		
5.55	230	—
8.25	225	—

A man, aged 58, had been admitted for epistaxis; he had some albuminuria and a hypertrophied heart; pulse, 78; blood pressure, 230. On low diet the pressure dropped to 135, and then rose to 143; after half an ounce of whisky it rose in six minutes to 150, and fell gradually to 135, at which it remained for the rest of the evening, and was at that figure at 10.15 the following morning.

Another man, aged 39, who had been a heavy drinker and smoker, was admitted with mitral disease and dropsy. There was a faint haze of albumen; pulse, 100; blood pressure, 160. On June 5th he had half an ounce of alcohol; 15 minutes later the blood pressure had fallen to 150, and 1½ hours later to 145.

A man, aged 43, with aortic and mitral disease, and of alcoholic habits, whose urine contained a trace of albumen, had a pulse of 116; blood pressure, 140; some time after admission his pulse was 60; blood pressure, 145.

Time.	Blood Pressure.	Pulse.
12.7	145	60
Half an ounce of whisky with soda water.		
12.23	170	44
12.33	140	46
1.13	135	45
1.57	150	60

The pressure remained at the last figure late in the evening, and was still the same the following morning.

Lastly, a man, aged 35, suffering from aortic disease, of alcoholic habits, with albuminuria; pulse 80, and blood pressure 140. Some weeks after admission his pulse was 60, blood pressure 165. Half an ounce of whisky with soda water:—

	Blood Pressure.	Pulse.
After 10 mins.	168	54
,, 20 mins.	145	58
,, 35 mins.	145	56

The following morning his pulse was 76, blood pressure 150.

On looking over these figures, it will be seen that, although, as a rule, a slight rise of pressure occurred a few minutes after taking the whisky, the rise was slight, and not more than might have been caused by the absorption of a certain amount of fluid. In the case of the healthy man there was a slight initial fall, followed by a slight rise, and then another fall. In most the initial rise was followed by a fall, and in only one was the pressure permanently raised—viz., in the case of advanced Bright's disease with dropsy.

In all the cases where a record has been kept, the pulse rate and the blood pressure have risen and fallen together.

On the other hand I do not find that chronic alcoholism, where it has not been complicated by Bright's disease, causes permanent high blood pressure; indeed, where the patient's general health is falling off, it may be quite low, as in the case of a patient, aged 56, suffering from chronic alcoholism, with gastritis and enlarged liver. His pulse was 114, and blood pressure 125; another patient, aged 36, with the same condition, pulse 84, blood pressure 125; a third, aged 64, with cirrhosis and ascites, after the ascites had disappeared, pulse 96, blood pressure 145.

Tobacco.

The statement has been frequently made that smoking tobacco raises the blood pressure and consequently embarrasses the action of a weak heart. I do not doubt that there is sufficient clinical experience to warrant us in continuing to give advice to patients who suffer from weak hearts, whether due to valvular disease or not, to smoke little or not at all, but the sphygmomanometer does not show any marked alteration in either pulse or blood pressure, after smoking.

Hesse has undertaken a series of experiments in order to determine whether tobacco exercises any direct influence upon the circulation. The subjects of these experiments were partly medical students and partly patients in hospital. The state of the blood pressure and the frequency of the pulse were noted before, during, and after smoking one, two, or three cigars in succession. In 17 out of 25 cases there was a slight increase of the frequency of the pulse, associated with a rise of arterial pressure, which was sometimes marked; in five the rise of pressure was unaccompanied by increase in the frequency of the pulse, and in three the blood pressure fell slightly, while the pulse frequency rose a little. It was noticeable that the chief increase in blood pressure occurred in subjects whose ages were from 45 to 57 years, while in young people the alteration was much less marked, so that it would appear that when the organism is young it adapts itself more readily to the injurious effects of tobacco. The result was influenced by the presence of certain organic diseases, especially pulmonary emphysema. It is important to observe whether the subject is, or is not, used to smoking tobacco; it would naturally be supposed that the effect would be more marked in the latter case, but it did not appear to be so, although the number of cases in which the point was tested was too small to enable any definite conclusion to be reached. The effect of tobacco on both the blood pressure and the pulse frequently reached its maximum at the end of from twenty to forty minutes when they returned to the normal limits. In three instances, after the experiment, a slight accentuation of the aortic second sound was observed.

The observations that I have been able to make have been few in number, but so far as they go they tend to show that at any rate in the case of habitual smokers the effect of the use of the weed on the blood pressure is slight. The first case was that of a man who is a tolerably heavy smoker and whose blood pressure at 9.34 a.m. was 140; pulse 84; in the course of the day he smoked half an ounce of hand-cut tobacco and two pipes of twist. His pulse and blood pressure were taken at intervals with the following results:—

Time.	Blood Pressure.	Pulse.
10.35	144	82
12.15	140	84
6 p.m.	160	84
Next morning.		
9.40 a.m.	140	84

No doubt this table shows a rise of 20 mm. at 6 p.m., but in this man's case the blood pressure has been frequently even higher; there is no reason to ascribe it to smoking, as he was an habitual smoker and began to smoke in the morning directly after the blood pressure was taken at 9.35, so that any effect due to tobacco should have been observed earlier in the day.

The other man smoked daily a quarter of an ounce of tobacco. His blood pressure was as follows:—

Time.	Blood Pressure.	Pulse.
9.30 a.m.	120	60
10.40	120	72
12.15	100	80
6 p.m.	120	74
Next morning.		
10 a.m.	120	68

In this case there seems to have been a slight acceleration of pulse with lowering of the blood pressure as the result of smoking. These subjects were elderly men; the first was a case of polycythæmia and the second one of chronic diabetes; both men had been for long under observation. The diabetic patient is weak, and is probably suffering from the degeneration of the heart which occurs in advanced cases.

Diabetes.

According to Potain diabetes is a disease accompanied by high arterial tension, his average being 220 in hospital patients, and 260 in private practice, with a minimum of 100 and a maximum of 310!

On the other hand, Vaquez in his report to the Seventh French Congress of Medicine (see *La Semaine Médicale*, 1904, p. 339) insisted on the fact that the tension is normal in many cases.

J. Teissier thought cases with increased tension generally belonged to the class of fat diabetics, while those with low tension were the cachectic type, or those complicated by phthisis.

Ambard (*Semaine Médicale*, 1906, p. 362) said that the cases with high tension were those with albuminuria, although all cases with albuminuria did not show high tension.

Severie (Paris Thesis) has studied 29 cases of diabetes and two of diabetes insipidus; the maximum was 240 and the minimum 90. Those with high tension were either cases of marked Bright's disease or gouty or arterio-sclerotic patients, with or without albuminuria. The tension varied from 190 to 240. Another case was at the same time arterio-sclerotic, albuminuric, and tubercular; the tension was at first 180, and fell rapidly to 120, and death occurred suddenly. Another patient, diabetic for four years, showed some signs of early phthisis at the left apex and had had hæmoptysis, yet his tension was 220. These examples show that pulmonary tuberculosis does not necessarily lower the blood pressure. The majority of diabetics who were neither emaciated, nor albuminuric, nor arterio-sclerotic showed a blood pressure about normal (?) 160, 170, or 180; in one case the tension was as high as 190 in a man of 50 (he was passing 153 grms. of sugar daily), and as high as 240 in another patient, aged 54, with neither cardiac nor pulmonary trouble nor albuminuria.

Those with low tension were chiefly tubercular. Ten tubercular diabetics had tensions ranging from 100 to 150, the average being 129. But cases showing marked failure of nutrition, with rapid cachexia, even when free from tubercle, occasionally showed low tension. For example, a man of 55, whose diabetes was only of 14 months' duration, had lost 50 lbs. in weight, and, in spite of diet, passed 204 grms. of sugar in 24 hours; his tension was only 120 to 130; another man of 33, passing 8 to 10 litres daily, with 600 to 900 grms. of sugar, in spite of diet, had a tension at first of 200 to 270, falling rapidly while the cachexia made progress, and was only 90 when he died. Cases of tubercular diabetes show a rapid fall of tension a few days before death, and it may be said that a marked low tension is always a bad prognostic in diabetics, whether the patient is or is not tubercular. On the other hand, high tension is not a specially grave indication, unless it rises to about 250, when it should give cause to fear various complications, especially cerebral hæmorrhage; but the fat type of diabetic may often present a tension of 190 to 210 without involving any immediate aggravation of the diabetes. Such are the conclusions arrived at by Dr. Severie.

I have studied the blood pressure in 25 cases of diabetes, of which 7 were albuminuric. The maximum blood pressure was 180, and the minimum 110; the maximum of 180 was reached, but not exceeded, in both albuminuric and non-albuminuric series. The lowest pressure amongst the albuminuric cases was 120, but this patient was tubercular, and it occurred soon before his death. Of the non-albuminuric cases the lowest was 110; this was also a few weeks before the death of the patient, who was not tubercular, but old (67), weakened and worn out by the disease. The average pressure amongst the albuminuric cases was 143, and the non-albuminuric cases 139, but the albuminuric cases were on the average considerably older (50) than the non-albuminuric cases (38). The only tubercular case was among the albuminuric patients, and his low blood pressure had some effect in reducing the average. One death occurred in each series, and each fatal case gave the lowest recorded pressure. The conclusion to be drawn from these cases is that a low pressure (below 130) is of bad prognosis, and is only met with in cases which have not long to live, but a single observation must not be relied upon, as a neglected patient may be run down and weak, and his blood pressure be very low, but after treatment he may recover, as in the case of a man I have at present in hospital; yet such a drop indicates that the case is grave and the condition serious, as it undoubtedly was here, for it was accompanied by loss of weight and di-aceturia.

Heart Disease.

Nothing is more paradoxical than the figures given by the sphygmomanometer in cases of heart disease, for even when uncompensated and requiring the patient to be confined to bed, the pulse tension sometimes is above normal, often normal, less often slightly reduced, and rarely or never lower than 110 to 115, except in children. In aortic regurgitation pressure may be quite high (210 to 220), and it was never less than 125. In some cases of mitral disease it was as low as 110 and 115, but was usually about 140, and occasionally as high as 180. Apparently the heart keeps the circulation to the normal level so long as it continues to beat, in spite of valvular disease or even grave lesions of the myocardium. A case of angina pectoris in a man aged 50 showed a blood pressure of 210 and a pulse of 60; there was no albumen in his urine, but he had used alcohol and tobacco. In leucocythæmia, simple anæmia, and in Hodgkin's disease, the blood pressure was low, but never much below normal limits, the minimum being 110 in a case of slight anæmia, with marked debility.

Bright's Disease.

As might be expected, it is in Bright's disease that the sphygmomanometer gives most marked departures from the normal, but it is only in chronic nephritis that high readings are constant. In acute and subacute cases the blood pressure is often normal, and I think it might be said that in cases that look like acute or sub-acute nephritis, where the blood pressure is over 160 or 170, the probability is that the case is one of chronic nephritis, upon which an acute or subacute attack has supervened. On the other hand, cases of nephritis where the blood pressure is not high are those not complicated by cardio-vascular disturbances. A high blood pressure may fall before death, as it did in a case of cardiac hypertrophy complicated by pericarditis, where it fell from 190 to 175, and subsequently to 125. In chronic Bright's disease the blood pressure is over 160 or 170, and may reach or exceed 300, which is the limit of the scale on the instrument.

Uric Acid.

There is an impression generally entertained that patients whose urine deposits uric acid suffer from high blood pressure, but so far as I have been able to observe such cases, I do not think there is any necessary connection. A boy, aged 9, in the hospital under my care, passed uric acid very persistently, but his blood pressure was never more than 110, pulse 72. Two brothers, aged 16 and 17, pass uric acid constantly in large quantities; the younger has a blood pressure of 120, pulse 72, and the elder, blood pressure 145, pulse 54. A man, aged 56, is gouty, and his urine constantly liable to deposit uric acid; his blood pressure is only 145, and pulse 72. A soft large pulse is, moreover, commonly met with in gouty people. Seven cases of headache were associated with uric acid; of these three were males and four females; three were over 40 years of age, and four under. One only showed a pressure over 150 mm., but that case was a woman with albuminuria; one only was below 120 mm., a boy aged 14; the rest ranged from 120 to 140, and were therefore within normal limits.

ORIGINAL PAPERS.

ON SUNDRY FORMS OF PSEUDO-RHEUMATISM OF TOXIC ORIGIN.

By M. S. LASSANGE, M.D.,

Of the Faculty of Medicine of Paris.

[Specially Reported for The Medical Press and Circular.]

The articular troubles which affect a similarity to rheumatism—acute and sub-acute polyarthritis—fall into one of two categories—*e.g.*, pseudo-rheumatism of infective origin, and true articular rheumatism. Apart from true acute articular rheumatism, which is, in all probability, a morbid entity caused by a specific organism, we sometimes meet, in the course of intoxications, with articular manifestations of an acute character which strikingly resemble true rheumatism. These may be grouped under the term pseudo-rheumatism of toxic origin. There are consequently three varieties of rheumatism—true articular rheumatism, infective pseudo-rheumatism, and toxic pseudo-rheumatism.

PATHOGENESIS.

Bacteriological research has not as yet determined the specific organisms of rheumatism, so that we are tempted to look for what our forefathers called "the peccant humours," which, in the light of our present knowledge, may be taken to mean toxins, poisons which are elaborated in, or introduced into, the organism, and set up changes in the blood, lymph, and intercellular plasma. As a matter of fact, the nature of these poisons has not as yet been clearly defined; yet the predominating factor in the pathogenesis of toxic pseudo-rheumatism is individual predisposition. This predisposition, which amounts to a genuine idiosyncrasy, has for effect that the individual will suffer from more or less marked rheumatic manifestations in the course of an intoxication which in another would be wanting, and its place taken by a toxic eruption. We recognise this predisposition without being able to define it. It may, of course, be inherited, but what is transmitted is not rheumatism itself but rather a predisposition to contract that disease. Are there not, however, toxins which, when present in the blood, exert a selective action on the joints? It is highly probable that such is the case, for in these cases the poisons attack the articular and peri-articular structures, setting up inflammatory lesions characterised by pain, swelling, and loss of function, and determine complications in the big serous membranes —endocardium, pericardium, pleura and meninges. It is therefore impossible to gainsay the selective action of certain poisons on articular and peri-articular tissues, but this influence does not always manifest itself, and, moreover, it does not explain all cases. It is probable, too, that in many instances the articular troubles in toxic pseudo-rheumatism are consecutive to changes in the nervous system brought about by the intoxication. This is not a new view, for Reveillé-Parize wrote:—"There is one view which was at first lost sight of, for it goes very far back, but is now rapidly gaining in favour. Many practitioners hold that rheumatic and muscular pains, whatever their distribution, are originally dependent on an affection of the spinal cord, this being manifested by the sensitiveness of certain points in the spinal region." This view is admitted by Friedlander, and recently by Trollard, of Algiers. It may consequently be conceded that the poisons are capable of acting on the articular centres of the spinal cord, in support of which view may be mentioned the frequency of polyneuritis, paralysis, and psychical disturbances in the course of various intoxications.

CLINICAL DATA.

We will begin with the exogenous poisons that may determine arthropathies simulating rheumatism. Alimentary toxins often give rise to pseudo-rheumatism of variable severity, which Bouchard believes to be due to the ingestion of the ptomaines and toxins present in decomposed meat. Friquet, in his thesis, collected numerous instances of alimentary intoxication followed by articular pain and synovial exudation which proved refractory to the salicylates. Moreover, instances are on record in which alimentary intoxication has given rise to epistaxis, dry pericarditis, double pleural effusion and mitral endocarditis.

Certain medicinal poisons—chloral, quinine, antipyrine, copaiba, and iodoform—have been known to cause similar symptoms. According to Fraser, eserine, and, according to Gubler, colchicine, may also determine joint pain with profuse sweating. In cases of accidental poisoning articular disturbances have often been noted, as, for instance, in chronic poisoning by arsenic or copper. Lead poisoning deserves special mention in this connection, for not only do we get plumbic gout, but also acute attacks of joint pain, which Sauvages describes collectively under the term metallic rheumatism. The joints and muscles become very painful, and the symptoms are most severe at night. The etiology of all these cases is certain—viz., an intoxication which is or is not grafted on a pre-existing diathesis.

Articular affections due to endogenous poisons may be dependent on many causes. Of the poisons thus formed within the organism, some are due to vitiated metabolism. Under ordinary circumstances these poisons are eliminated by the emunctories without any trouble, but in presence of fatigue, over-work, and certain external causes the secretion of these toxins is increased by organic changes, and if the normal paths of elimination are obstructed, we are apt to get morbid disturbances, more particularly articular fluxions. This, indeed, was the reason that led our predecessors to ascribe an attack of rheumatism to the sudden suppression of normal or accidental evacuations, such, for instance, as profuse or local perspiration. When the bye-products of metabolism accumulate in the blood we get the uræmic state, and one variety of this uræmia is arthralgic, as to which Jaccoud says:—"This form must be rare, to judge by the silence of authors in respect thereof, but I wish to call attention to it, not as something new, but especially because it may tend to render the diagnosis obscure. I remember the case of a woman suffering from chronic kidney disease who was seized with very severe pains in all the joints. Next day she developed uræmic convulsions, which soon merged into coma; yet the joint pain persisted, for, even when coma was complete, pressure on the articulations was the only thing that changed the expression of her otherwise impassive face. At the same time she made reflex attempts to get away from the painful pressure. In another case, one in which the patient was found comatose in the street, pressure on the knees and other joints provoked inarticulate cries and contraction of the facial muscles. On examining the urine, we found it laden with albumen, and containing numerous casts. Post-mortem examination confirmed the diagnosis of renal disease." These joint pains occur not only in uræmia, but also in Bright's disease, showing that renal elimination is inadequate.

But even when the kidney is working properly, accumulation of the poisons may still take place if they are produced in too large quantities. In this connection we must examine the two principal sources of organic poisons—viz., a disordered digestive tract and microbial foci.

Digestive auto-intoxication has been thoroughly investigated by Bouchard, and among the disturbances consequent thereupon we get articular affections, not to speak of osseous deformities in the extremities (Heberden's nodes), or of slowly progressive joint troubles, reserving our attention for the more acute manifestations. These troubles, which may be associated with digestive disturbance, or may alternate therewith, present the greatest analogy with ordinary rheumatism. The articular pain is accompanied by loss of appetite, furred tongue, palpitations, dyspnœa, constipation or fœtid diarrhœa, often associated with disagreeable dryness of the throat.

The practical conclusion to be drawn from these facts is that, in the etiological examination of rheumatic manifestations, we must always bear in mind the possibility of digestive disturbances, and, when found to be present, instead of giving irritating medicines which would aggravate the condition, we must institute an anti-dyspeptic regimen and clear the intestines by repeated saline laxatives. This method of treatment will often succeed when the specific medication fails.

The so-called bilious rheumatism which occurs in the form of acute or sub-acute polyarthritis in the course of biliary cirrhosis or common cholemia, belongs to the same group. Rheumatism occurring during pregnancy is also probably a manifestation of gravid intoxication.

Now as to the microbial toxins. Can they determine similar arthropathies? We are hardly justified in asserting that such is the case; yet instances are on record in which pseudo-rheumatism associated with certain infections has been shown to be of toxic origin. When for therapeutical purposes we employ attenuated microbial toxins or the serum of an immunised animal, we not infrequently get eruptions and joint pains which are due to the seropathy. Articular pain strikingly resembling that of rheumatism is particularly frequent after injections of tuberculin and anti-diphtheric serum. Poncet, who has made numerous subcutaneous injections of tuberculin, looks upon these accidents as the result of intoxication induced by Koch's lymph, and he compares them with the outbursts of articular rheumatism which he has met with in non-rheumatic phthisical subjects supervening when the cough and expectoration have been arrested. He says:—"If, under the influence of a too efficacious medication, the natural emunctory represented by the expectoration is suppressed, the retention of pus and tuberculous products in the cavities gives rise to auto-intoxication. In such cases retention is an exchangeable term for absorption—*i.e.*, permeation of the organism by toxins produced in the pathological focus from which they can no longer make their way out. Articular complications may, under these circumstances, supervene in the form of acute articular rheumatism."

The toxic origin of certain rheumatoid arthropathies following the injection of anti-diphtheric serum was first called attention to by Dr. Moizard. In 1895 Gaillard brought before the Hospitals' Medical Society a case in which acute polyarticular rheumatism set in a fortnight after an injection of anti-diphtheric serum in a patient who had streptococcic angina, and was attributed by the author to the direct action of the injection. A child of 5 who had been given a similar injection by Dr. Sevestre developed a rosy eruption on the back of the hands, and the joints became swollen, with pain in the neck and vertebral column. Many such cases have since been placed on record, and the toxic origin of the articular troubles is now generally admitted. It follows that microbial toxins, even when the organisms themselves do not find their way into the joint, may give rise to arthralgia like that of rheumatism, and we can understand the distinction made by Poncet in respect of tuberculous rheumatism:—"Apart from specific or plastic tuberculosis with typically tuberculous products, there is an inflammatory tuberculosis which often assumes a rheumatic aspect. The bacillus is in this case wanting, and the case is one of toxic but not bacillary arthritis."

The same procession of events is seen in blenorrhagia and scarlet fever. Sometimes the articular manifestations are due to the intrusion of the microbe into the joint, and when this follows scarlet fever there is serous suppurative arthritis or suppurative arthritis *ab initio*, while in blenorrhagia we have pseudo-phlegmonous arthritis. In the other cases we get more or less disseminated polyarthritis, never followed by suppuration, in which bacteriological examination gives negative results.

CONCLUSIONS.

In all the cases referred to, the etiology of the articular manifestations is characterised by an intoxication bearing on subjects possessed of a special morbid predisposition which it is difficult to define but the existence whereof is incontrovertible. In some instances the intoxication is obvious, and constitutes the sole cause that can possibly be invoked, as when the poisons are of extraneous origin—*e.g.*, taken with the food, or in medicinal form, or by accident. In other cases the arthropathy appears to be due to toxins elaborated within the organism. In the last-named the intoxication is unquestionable, and its influence in the production of articular manifestations approximately certain, as has been shown, but it is then much more difficult to define the exact origin of the poison by reason of the complex and multiple reactions of the tissues.

But in virtue of what mechanism do these exogenous or endogenous toxins determine rheumatoid phenomena? In the present state of our knowledge, no answer can be vouchsafed, so we are fain to content ourselves with suggesting various plausible hypotheses based on the study of the pathological conditions. Moreover, it is highly probable that the mechanism varies according to the nature and the quantity of the poison.

However this may be, all the recorded cases present certain points of resemblance. Cases of toxic pseudo-rheumatism all have a certain family resemblance. Their analogy enables us to classify them and to differentiate them from a whole series of arthrites due to the presence in the joints of an infective agent.

Toxic pseudo-rheumatism may take the form of simple arthralgia or actual rheumatism strictly comparable with true rheumatism. The onset is sudden, is characterised by pain in a certain number of joints, remaining polyarticular for several hours, but soon becomes more pronounced in one or two big joints which remain affected longer than the others. The pain alone may persist, and it presents certain peculiarities. It resembles that of true rheumatism, as described by Lassègue. It is not really an intra-articular pain, but a sensation of burning tension or arthralgia around the joint, corresponding to the insertion of tendons or of the muscles covering it. Movement is more painful than pressure of the joint. The inflammatory phenomena that accompany the pain are, as a rule, not very pronounced; there is but slight swelling and redness, and intra-articular effusion, though possible, is exceptional. In short, it may be said of toxic rheumatism, in respect of the local symptoms, what Lassègue said of true articular rheumatism—viz., "that they are especially extra-capsular, whereas infective arthritis is essentially intra-capsular."

The characteristic physiognomy of toxic rheumatism is not exclusively due to the local symptomatology. Although in some instances they may seem isolated, and although the more or less severe articular pain sometimes constitutes the whole symptomatology of intoxication, in the majority of instances the arthropathy is only one feature of a whole category of disturbances usually regarded as of toxic origin. The most striking are the cutaneous manifestations so frequently met with in association with various intoxications—profuse sweating and diverse eruptions, prurigo urticaria and polymorphous erythemata.

The course of toxic pseudo-rheumatism is sufficiently characteristic. The acute attacks are remarkable for their comparative mildness, their ephemeral duration, and the variability of the phenomena. But in the long run, should the attacks be repeated, as may happen in the course of chronic intoxication, it ends by the formation of plastic products manifested by crackling, with dull, persistent pain.

These characters and this course enable us to distinguish the arthropathies under consideration from the microbial arthrites which only attack one joint, or only a few joints, remain localised therein, and are often followed by suppuration.

To conclude, it may be stated that a poison that has permeated the organism in predisposed subjects may give rise to articular disturbances very similar to those of true rheumatism, and these rheumatoid phenomena resemble each other closely enough for it to be justifiable to classify them in a special group—the group of toxic pseudo-rheumatism. Lastly, although it was not our object to revive the theory of the toxic origin of ordinary articular rheumatism, such theory being notoriously inadequate, it is probable that the causes of toxic pseudo-rheumatism, together with the cases of infective pseudo-rheumatism, will be found to cover the great majority of cases still regarded as true articular rheumatism. For, should a specific agent be discovered in this affection, it will always be possible to relegate it to one or other of the two groups of pseudo-rheumatism already established. In some instances, indeed, this agent may be localised in a joint and set up a rheumatic arthritis, this being an infective accident; in other cases, when the blood merely conveys poisons elaborated by this agent in the tonsils, or perhaps in the intestine, these poisons may, either directly or *viâ* the nervous system, act upon the joint structures and give rise to purely toxic arthropathies.

THE RAVAGES OF TUBERCULOSIS IN IRELAND. (*a*)

BY R. F. TOBIN, F.R.C.S.I.,

Surgeon to the Hospital.

THE statistics of the death-rate from this disease, the only official information we have of it since it is not notifiable, are pretty generally known. Still, as you may not have meditated on them as you should with your morning prayers, I shall briefly lay them before you. I quote the Registrar-

---

(*a*) Being a Lecture Introductory to the Session 1907-8 of the Medical School at St. Vincent's Hospital, Dublin.

General. In his report for 1906, under the head of tuberculosis, he says:—"I find that there were 11,756 victims, inhabitants of Ireland; in other words, out of a total of 74,427 deaths registered in Ireland during the year 1906 no fewer than 11,756, or 5.8 per cent., were sacrificed to a disease which is in a great degree preventable. Year after year these facts are published, and although the members of the medical profession are strenuous in trying to awaken the public to a state of affairs that can only be considered as destructive to the community, yet, comparatively speaking, our countrymen are not alive to the dangers which threaten them." In another part of the same report he points out that "by far the greater number of the descendents were in the effective age periods of life, the highest number for both sexes falling in the age period between 25 and 35 years." In another column the average annual death-rate from tuberculous disease during the last five years is shown to be over 12,000.

Now, it has been calculated that the ascertained mortality from tuberculous diseases may be safely multiplied by ten in order to represent approximately the number of persons living and seriously affected in the area in which the deaths occurred. Doing this with the figures before us we arrive at the appalling fact that there are at this moment 120,000 people scattered over this country suffering in a more or less advanced degree from this infectious disease. In my opinion this calculation is under the mark, for patients suffering from tuberculous disease in outlying parts of the body are much more numerous than patients suffering from phthisis pulmonalis, and they generally live a long time. It is also interesting to compare the statistics of population, and of disease, in Ireland and Scotland. On doing so during the last sixty or seventy years we find—I am roughly speaking—that while in Scotland tuberculous disease has fallen one-half, and the population has doubled, the reverse is the case in Ireland. Tuberculosis has markedly increased, and the population has fallen one-half. Surely these are facts we should let sink deeply into our consciousness. Now, carry your attention to this further view of the situation. You are all aware that in actual warfare the degree to which the effectiveness of an army is diminished by deaths, wounds, and disease is not computed by merely substracting the loss so occasioned from the total strength. There are other factors to be considered. The effects on the morale of the troops of a large sick rate and death rate, the numbers required to wait on the sick, the degree to which their transit blocks the lines of communications, the extent to which they in various ways hamper the efficiency of the men in health. All these have to be taken into account before you can judge of the degree to which sickness impairs effectiveness. Will anyone say it is different in civil life? That the sick child or the sick wife doesn't hamper the whole household, that the morale and earning power of its strongest hand is not impaired by the weak one; that he is not a depressing influence far beyond his own home. You, no doubt, feel inclined to interrupt me by saying:—"We have all felt it, we all know it." My answer is, measure it, multiply it by one hundred and twenty thousand, and there you have the extent of an omnipresent force called into existence by these bacilli over and above the killed and wounded that they claim. It is, as I have said, an appalling bill. It raises the question, is not this the question of questions and ought not all other questions stand aside until it is solved?

It is now some years since Pasteur gave to this world an announcement which stands only second to another "message of great joy," and one, the truth of which, as time goes on, is more and more recognised by the scientific world. "A day will come when in Berlin, in London, in Paris man will not die of diphtheria, of typhoid, of scarlet fever, of cholera, or tuberculosis any more than he dies in these cities to-day from the venom of snakes or the teeth of wolves." It is interesting to contemplate the different use made of the scientific fact contained in this announcement by two distinct nationalities. We, who are imbued with the conceit and pusillanimity of Western civilisation, heard it and went our way on motor cars, tram cars, bicycles, shoe-leather and bare feet as if nothing at all had been said. So much so that when Sir Frederick Treves repeated this same sentence quite recently, we received it as something quite new, and he had to write to the papers to say that it was to be found at page 129 of Frankland's "Life of Pasteur." Japan also heard it, as it lay in terror of extinction by the Muscovite flood then spreading in the East. Dare they draw the sword on Russia? If they were to do so they would lose 50,000, perhaps, 100,000 in fair fight. They were satisfied to bear that loss. But what of deaths from disease? They knew the following figures collected from the history of warfare, "of every hundred men lost in war twenty die from fair fighting, eighty from disease." I can answer for these figures, for I was assistant to Longmore when he was compiling the tables that bear his name, and on which they are founded. With these statistics before them the drawing of the sword seemed hopeless. Fifty thousand deaths from wounds meant an additional two hundred thousand deaths from disease, and putting the mortality as high as 1 in 10, this number of deaths from disease meant two million cases of sickness. If you call to mind what I have already said of how a large sick list in warfare interferes with effectiveness, especially when operations have to be carried on at a distance from the base, you will see that their case was hopeless. It was a pitiable state of things, for the love of race was strong in them. Then they heard the message of Pasteur. They realised what could be done by a successful application of his discoveries. We know the rest. We know where Japan stood then and where she stands now, but listen to the figures of the fight. I give them from a book I would advise everyone to read, "The Real Triumph of Japan," by L. L. Seaman, who was in the position of a military attaché to the Japanese Army during the war:—52,946 killed in fair fight, 11,992 killed by disease. They are results that cry "pause" to European civilisation. Let me indicate the main features of the measures by which these results were obtained. The medical profession was placed, as regards position and power, not above or below, but on a level with the other great departments of the State. So placed it was found worthy of the trust reposed in it. Its members studied not Squire's Pharmacopœia and the Dictionary of Treatment, but the works of Pasteur and Koch and Parkes and their many followers. Sanitation was made the first duty of medical officers. If a regiment with one medical officer was engaged in an action on its way to a certain camp, and there were, say, twenty wounded, the surgeon on arrival allowed the wounded, to whom, when they were picked up, first dressings had been applied, to lie on their litters till he had looked into everything likely to affect the health of the men. The water was tested, and the wells marked fit or unfit for drinking. If there was no good water, what there was was filtered or preferably boiled, and, rice being added, it was both a safe and nutritious drink. So on with other things. Finally every soldier was given an elementary idea of the rules of health, and these soldiers (herein lies the strength of Japan) had the self-restraint and the patriotism to do what they knew was right. How do we act here? What of our knowledge and self-restraint and patriotism? We see a secret foe spreading over the country practically unopposed, killing and maiming and scattering its inhabitants.

As a race we are nearer to extinction than were the Japanese. What are we doing? Is the fate that threatens us the fitting outcome of our ineptitude? Here a word about the position of the medical profession in this crisis is required. Where are we, and what are we doing? We are in the position assigned us by the public, by whom, it is said, we are valued, but apparently not sufficiently so to induce them to make us responsible for the conduct even of affairs of health. We have no power and we have very little influence in the State. We are not men like judges, generals, magistrates, policemen, who draw their incomes from the public purse, and who are, therefore, from a pecuniary point of view independent of the good opinion of their neighbours. On the contrary, we, as a profession, are dependent for the means of living on fees received from individuals from day to day. The good opinion, therefore, of that representative person, the man in the street, not in a general, but in a particular way, is necessary to us. This notwithstanding, we are for ever preaching hygiene, temperance, and other unpleasant truths to people who don't want to hear. Can you expect more from us? Can you ask us to refuse you, after you have been duly warned, the thing you demand? Medicine is a great and noble profession; still its members have in them some human nature, and some appetites, for the satisfaction of which fees and not ideals are required. Now what do the public want in this matter of tubercular disease? They want treatment and liberty. Treatment according to some of the recognised forms, since there is no cure—liberty to scatter their bacilli over the land. Now as to preventive medicine. There are, I am told, only two men in the whole of Ireland who are paid to give their whole time as sanitary officers. There is also, it is true, a medical officer of health in every town and dispensary district; but you can only judge how far he meets the requirements of the situation when you know what is his salary—what his equipment. Has he a diploma in public health? and, above all, are his hands free?

Now let me sum up the case before you. There are in the country one hundred and twenty thousand cases of tuberculous diseases. An infectious disease, a preventible disease, a disease that means sickness extending over years, bringing death and disablement to those it attacks—sorrow and ineffectiveness to those who escape. This fact, made clear to us by statistics, is confirmed by the state of affairs in general. You can apply the term decline to the condition of the country as truly as you can to an advanced case of phthisis in the wards. Things will not mend of their own accord. On the contrary, if nothing is done, they will grow worse. For the disease is scattered everywhere, spreading its germs as a daisy does its seeds. That is the first point. The next is that means are at our disposal to tackle this great plague, but the great majority of the public do not care. They do not really care. They will not focus their attention on the question. There is no public purse-opening force in their sympathy. Their attitude is characterised by indifference and parsimony.

What is the first step in this state of things to be set right? Here are my views briefly. Nothing new, as I have already told you. Education, and again education, on the questions of public health for the cultured as well as for the working classes. Who is to be educated? Each individual Irishman. Not in any special way county councillors or members of Parliament, or even the English Government, but each man and woman and child who is given room on the land called Ireland. He is to be taught that health is the first duty, and the best economy, whether he considers himself or his country. Further, that the attainment of health consists in the carrying out of certain rules the enforcement of which lies partly at his door, partly with the corporations whom he elects to represent him. There will then remain only one question, "What About Compulsory Notification?" On this I hold very definite views. There are medium courses. Much could be done by admonition and supervision, especially if the number of nurses throughout the country were increased. One thing, anyhow, is certain —if notification were made compulsory, we would in a few years have very valuable information about this disease. There is no knowing what points it might bring out. That information being obtained, the whole question should be considered by all the councils collectively. They should combine and call to their assistance the best advice the world can provide, and thereupon with full information before them, they should decide on what measures to take, just as if it were a question of drainage or of water supply.

There is much else to be said, but you will joyfully agree there are limitations to an address. We must, however, not let pass without recognition what many enthusiastic men throughout the country, what the Registrar-General, the National Society for the Prevention of Consumption, and the Women's National Health Association of Ireland have been doing.

THE SPONTANEOUS FRACTURE OF URINARY CALCULI. (*a*)

By T. R. BRADSHAW, B.A., M.D., F.R.C.P.,

Physician to the Liverpool Royal Infirmary.

THE occurrence of spontaneous fracture of a urinary calculus followed by expulsion of the fragments through the urethra, though it has been recorded from time to time, is a comparatively rare event, and I think that an account of an instance I have met with in my own practice will not prove without interest.

The subject of the condition is a gentleman, now in his eighty-first year, who led an active professional life until ten or twelve years ago. About twenty years ago he began to pass small uric acid calculi *per urethram*, and this has continued at intervals up to the present. They were generally the so-called "mustard seed" calculi, but sometimes much larger. One, which is shown in fig. 1, passed in 1891, measures ⅜ in. by ¼ in., and weighs 325 mg., about 5 grains. The urine was almost always acid, and in every respect normal, except that it seemed deficient in colouring matter, and on standing deposited crystals of uric acid more quickly than usual. For many years there has been a good deal of irritability of the bladder, with frequent micturition at night; but there is little, if any, prostatic enlargement, and the urine is at the present time quite free from excess of mucus.

On October 22nd, 1901, hæmaturia was noticed for the first time, and it has recurred at intervals until the present. The quantity of blood was generally small; it was thoroughly mixed with the urine, and was most noticeable after exercise. It was seldom present in the morning, but was very frequently noticed after a walk of a mile or two, sometimes after a carriage drive. I came to the conclusion that my patient had a renal calculus, but, in consideration of his advanced age, and of the fact that his general health was not compromised, I did not entertain the idea of operative interference.

On January 5th, 1905, Mr. T. T. Holland took radiographs, and determined the presence of two calculi in the right kidney. After this the patient began to suffer from occasional painful attacks in the right side of the abdomen, attended with tenderness in the right iliac fossa, and slight pyrexia. Whether these were due to renal colic or to appendicitis there was a good deal of doubt, but on May 30th, 1905, he was suddenly seized with an agonising pain in the right side of the abdomen, which was undoubtedly of renal origin. Similar slighter attacks followed. In January, 1906, he began to pass fragments of calculus, and continued to do so during several months. At the same time his general health improved. He found he could take exercise without inducing hæmaturia as readily as before. In his own words, he felt as if he had got rid of something. On June 1st, 1906, he had a rather sharp attack of renal colic, and on June 16th he began to pass fragments, and continued to do so for a few days. These, when collected, weighed about 14 grains. One can hardly doubt that the colic of June 1st was connected with the descent of a calculus which disintegrated, and was evacuated piecemeal. Again, last November, more fragments appeared.

As to whether this process is likely to end in the complete removal of the calculi, I am not prepared to offer a positive opinion. I can only say that my patient can now (May, 1907) take his usual exercise with a degree of immunity from bleeding which he has not enjoyed for some years past.

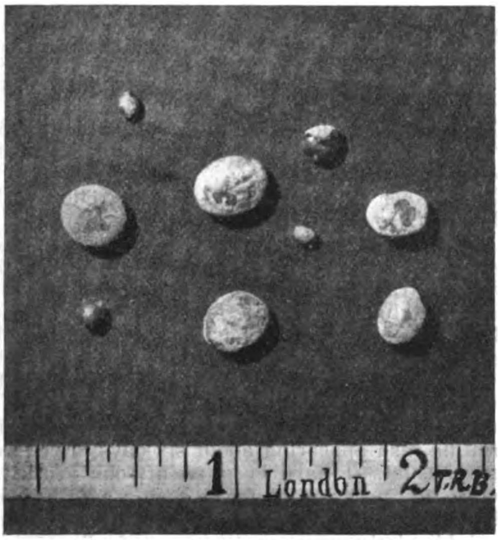
The treatment adopted was extremely simple,

(*a*) Paper read before the Liverpool Medical Institution, November 22nd, 1906.

the object aimed at being to reduce the nitrogenous intake to the smallest amount compatible with the maintenance of nutrition, to keep up a flow of urine, and to maintain the general health by moderate exercise, regularity of life, and the avoidance of fatigue. When the uric acid calculi first appeared, my patient, always an abstemious man, reduced his diet still further. He became to a considerable extent a vegetarian, lunched chiefly on milk puddings, seldom touched butcher's meat, dined chiefly on white fish, and gave up drinking wine altogether. From time to time, especially when calculi were passed, he used to take small doses of citrate of potassium, 5 grains once or twice a day; never enough to make the urine alkaline.

The possibility of urinary calculi being got rid of by a process of spontaneous lithotrity, such as has been going on in my patient's case, does not seem to be generally recognised in text-books of medicine or surgery. I can find no mention of it in Mr. H. Morris's "Surgical Diseases of the Kidney and Ureter," nor in Prof. Osler's "Practice of Medicine." The late Sir Wiliam Roberts, in his great work on "Diseases of the Kidneys," discusses the possibility of dissolving calculi, but does not allude to the possibility of their breaking up. Nevertheless, several cases are on record. Dr. Prout (1), in 1848, speaks of several instances as having fallen under his notice, and describes at length one case, that of a gentleman, æt. 90, who, after suffering from symptoms of stone in the bladder, began to pass fragments of uric acid which had evidently formed portions of a calculus, and continued to do so occasionally for more than a year. In the museum of the Royal College of Surgeons there is an example of spontaneous fracture which was met with in the practice of Mr. Southam, and in 1876 a case was related to the Pathological Society by Dr. W. M. Ord (2). This patient, a gentleman, æt. 83, passed an enormous number of fragments, which appeared to be segments of multiple calculi, consisting of uric acid and urates. Subsequently Dr. Ord reported several other cases in his own practice and that of others, and ten cases were classified and collated by Wilberforce Smith and E. Hurry Fenwick in 1890 (3).

Fig 1.



Scale of Inches.

Another notable case was that of Kraus, of Carlsbad, where a man, æt. 78, some months after undergoing the "kur," passed fragments representing the débris of nearly thirty calculi (4).

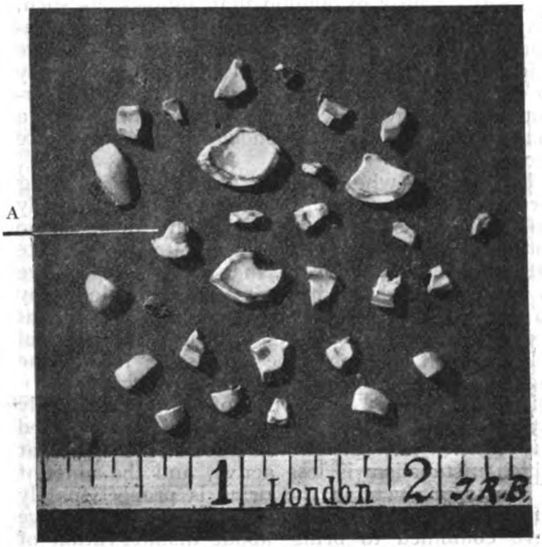
At the Egyptian Congress of Medicine, 1902, Mr. Reginald Harrison reported a case where a gentleman undergoing treatment with borocitrate of magnesia passed a large number of fragments, and I believed it is claimed for various spas that the same result may follow the use of the waters.

Two questions present themselves. By what means is the fragmentation brought about, and is it possible to promote its occurrence by therapeutic measures?

1. Dr. Ord (5), noticing that the nucleus was absent from every fragment which he examined, suggested that an expansion took place in the nucleus and led to disruption of the calculus, as of a shell by a bursting charge. Opposed to this view is the fact that one of my specimens shows a perfect nucleus lying *in situ* with a large fragment attached to and partly enveloping it (see *a* in fig. 2).

2. Dr. Ord thinks that in one case he found the mycelium (6) of a fungus growing on the fractured surfaces. If this was the cause of the breaking up of the stone we must admit the possibility of various agencies bringing this result about.

Fig 2.



Scale of Inches.

At A is seen a fragment with nucleus attached.

3. A varying degree of acidity of the urine has been supposed to cause solution of certain of the layers of a porous stone by undermining the superficial parts. Of this theory we may say that as varying degrees of acidity are the rule and not the exception, if it were true, spontaneous fragmentation should be much more common than it is.

4. Bigelow suggested that the human bladder can crush stones as the human hand can crush walnuts.

5. Finally, we have the old suggestion of Dr. Prout (7), elaborated in a somewhat different form by Mr. Plowright (8), that certain calculi have a distinct radial structure, with a tendency to lines of cleavage, running from the centre towards the circumference. Of the truth of this view anyone may satisfy himself by inspecting the uric acid calculi shown in section in a pathological museum. There are some excellent instances in the museum at the Liverpool University.

In reviewing the explanations offered, one is inclined to wonder, if they are true, why spontaneous disintegration of calculi is not a common occurrence, instead of being, as is universally admitted, an event of considerable rarity. The true cause must be a circumstance, or a combination of circumstances, rarely present in the subjects of calculi. Further, whatever the conditions may be, once established they tend to persist, for experience shows that when the fragments of calculi have once appeared we may expect a repetition of the occurrence during months or years to follow. Finally, there is strong reason to believe that uric acid calculi alone are capable of undergoing spontaneous disintegration.

Mr. Buckstone Browne (9), who reported two cases in 1890, puts the following leading question: "Does the alkali in the water of many a watering-place really deserve the credit of breaking up and bringing away stones; but, rather, is not the disintegration of the calculi due to their being bathed by healthy urine, the result of drinking freely of *water*, and of the fresh air exercise and somewhat restricted diet usually imposed on the frequenters of these health resorts?"

I am strongly of opinion that alkalies, as such, play but a very subsidiary part in the disintegration of calculi, and that the attempt to dissolve calculi by bathing them in alkaline urine is likely to defeat the object in view by leading to the formation of a layer of phosphates on the stone, a material which has no tendency to disintegrate spontaneously.

Dr. Prout, whose views as to the radiating structure of many uric acid calculi I have already referred to, points out that healthy urine is so constituted as never to be in a state of complete saturation even when cold, that at the temperature of the human body its point of saturation may be supposed to be still further raised, and that healthy urine is probably one of the most powerful solvents that we can hope to possess for all the ingredients likely to exist in urinary calculi. In this connection it is worthy of note that nearly every case of spontaneous disintegration recorded has been in a man who has reached an age at which metabolism is less active, and the amount of waste products in the urine is proportionately diminished. The circumstances which I believe have combined to bring about disintegration of the calculi in my case, and in others like it, are very simple, but, I suspect, not so frequently found together as one might suppose. They are the maintenance of the urine in a healthy condition, the presence in that secretion of abundance of water, and the reduction to a minimum of the products of nitrogenous waste.

Note.—Chemical analysis of the fragments shows that they consist almost entirely of pure uric acid. There are traces of sodium and ammonia. The fragments vary in colour from almost pure white to rich pink, but the majority are pale yellow ochre.

Addendum, October, 1907.—The patient remains in good health. During the last two months he has passed numerous fragments of uric acid calculi.

CLINICAL RECORDS.

ACUTE NEPHRITIS AND SCARLATINA.

By THOMAS P. CODD, L. & L.M., K.Q.C.P.I., L.R.C.S.,I., L.M.,

Rotunda, Dublin.

The following case which came under my observation may be interesting to some of your readers.

It was a case of acute nephritis, which developed afterwards into scarlatina. A girl æt. 11, pale, thin, and of a delicate nature, was brought to me by her father on August 8th, 1907, suffering from stomatitis, for which I prescribed a weak solution of Condy's fluid as a mouth wash. Three days after, her father left at my house a 4 oz. bottle of urine, smoky in colour. On examination, it was found to contain blood, and to be highly albuminous. He called in the afternoon to tell me that the child seemed apparently well, except the condition of the urine; that she was running about, and, in fact, he was going to bring her up to my house, not thinking there was much wrong. Being rather an anæmic child, I gave her a mixture of liq. ferri. perchlor., and recommended her to be kept in bed, and get barley water and a little chicken jelly.

I called to see her the next day. Pulse normal, temperature 99 deg. F., no sign of any rash whatsoever, but inclined to be sick.

The mother could not understand when I told her the danger the child was in, and that she should be kept in bed.

The mother said she would like the child to be in hospital, so the same day she was admitted to the children's hospital. On examination, they could not detect anything unusual (except for the urine); no rash or high temperature. Four days afterwards the father came to tell me that a rash had developed, which was pronounced to be scarlatina rash; consequently the child had to be sent to the Fever Hospital, Cork Street. The peculiarity of this case, acute nephritis setting in first, and with such trivial symptoms, and the scarlatina rash appearing about six days after, was most unusual. I have been twenty-one years in practice, and never came across such a case before; perhaps some of your readers have. I understand the child's kidneys are acting very badly at present, and are only secreting 2 oz. of urine in the twenty-four hours. The blood has disappeared, and the albumen still continues.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Case of Intestinal Obstruction.—Mr. Joseph Cunning operated on a girl, æt. 12, who had been admitted at midnight the previous night. She had gone to bed at 11 after eating a number of green pears during the evening. She woke about midnight with acute pain in the abdomen, vomiting and diarrhœa. She was then brought to the hospital. She was on admission suffering from colicky pains, with a short interval between, pulse 80, temperature normal. On abdominal examination, the right half of the abdomen and the hypogastrium were occupied by a swelling shaped like a stomach, and during the colicky pains this swelling became more prominent and hard. It was resonant on percussion; there was no tenderness over it or rigidity of the abdominal wall. Rectal examination revealed nothing, and there was no passage or either blood or mucus. She herself said she had had a previous attack like this twelve months ago, and that since then she had had occasional attacks of sickness in school, but no pain. An enema was given, but with no result. During the night she was sick two or three times, but only stomach contents were brought up. A diagnosis was made of mechanical obstruction, which might be due to a band, as a result of the illness twelve months previously, or the case might be one of volvulus. The question of intussusception had been considered, but the tumour, which could be felt, was much bigger than the swelling usually present in intussusception, and it remained localised to the right half of the abdomen instead of progressing in the direction of the colon, and there had been no passage of either blood or mucus. Mr. Cunning before operating demonstrated the swelling and its increase in prominence during a period of visible peristalsis, and pointed out that this must be due to hypertrophy of the intestine. He then opened the abdomen through the right rectus, and found the intestine adherent to the abdominal wall by fine filmy adhesions. On separating these extensively it was found that the abdomen was divided into two halves, the left being occupied by normal intestine, the right by intestine covered with sheets of adhesions like fine tissue paper, with the exception of the middle of the tumour, which was constricted by a thicker band of adhesions, thus accounting for the stomach-like shape of the swelling. During the process of separating these adhesions the collapsed ascending colon and cæcum were discovered to the outer side, and the appendix was exposed; this structure was found to be the seat of a previous attack of appendicitis, which had resulted in the sloughing of the greater portion of its extent so that only about an inch of it remained; this stump was adherent to the tumour, which consisted of ileum, and all the adhesions apparently were the result of this attack of appendicitis. The stump of the appendix was separated and removed. The tumour was then investigated, and found to be many feet of the ileum rolled up in a concertina or accordion-pleated shape, the coils being held together by fine "chiffon"-like adhesions. When the dilated portion of intestine was exposed there could be felt in it numbers of firm masses, which were evidently the hurriedly chewed green pears. All the adherent coils of intestine were separated, and the abdomen was closed in three layers after it had been filled with normal saline solution in the hope of preventing the re-formation of adhesions. Mr. Cunning said that it had been clear that the patient had suffered from some chronic obstruction for a long time; it might be that the attack twelve months ago was one of intestinal obstruction, or it might have been one of appendicitis, for the only information to be obtained was from the girl herself, and she was too young to be able to give a proper account of her malady; the attack of appendicitis might have happened years before. The present attack of complete obstruction was due to the impaction of a hard mass of green pears in the ileum which was already kinked by adhesions. A patient might have a very small lumen in the small intestine, and yet get along comfortably owing to the liquid nature of the contents, but if large indigestible masses were swallowed, impaction was likely to occur and cause obstruction. He remarked that he had operated at once, although it was possible, but hardly probable, that the patient might have overcome the obstruction, but the danger of waiting was that if she did not overcome the obstruction the intestine would have become distended, and not only would there have been more difficulty in performing the operation, but there would have been the added danger of invasion of the wall of the intestine by the bacillus coli, and therefore the risk of peritonitis. Again, when distended intestine has to be handled, it is very difficult not to produce abrasions of the peritoneum, which constitutes one of the great risks of operating on such cases. With regard to the adhesions present it was interesting to note that in some cases of large localised appendicular abscesses, which had been drained, when the abdomen was opened several months afterwards, the adhesions had almost entirely disappeared, yet in such cases as the present one there was apparently no attempt at the absorption of the adhesions. For this peculiarity he would not venture to offer an explanation.

TREATMENT OF GONORRHŒA.

In presence of a patient suffering from a urethral discharge, the practitioner should first assure himself of the nature and length of time the discharge has been observed. If he has good reasons to believe that the affection is recent, dating from two to three days at most, I am one of those, says Dr. Carle, who consider that in such cases the abortive treatment should be tried.

A treatment of this kind should produce, in 48 hours, a complete relief of the acute symptoms—congestion, abundant and greenish pus, pain, painful miction and erections. In five days the discharge should be reduced to a drop in the morning, and at the end of a fortnight all symptoms of the disease should have disappeared.

At the first visit Dr. Carle commences the treatment by injections of a solution of permanganate of potash (4 grains to the quart). With a syringe containing half an ounce of liquid, he makes a series of injections (four or five injections are sufficient), each retained a few seconds. Three hours after a second series is made by the patient himself, and repeated every three hours (day time) up to the sixth day. From the sixth to the tenth day three series of injections only per day, then two during the two or three following days, and finally only one, in the morning. After the fifteenth day, if no discharge is perceived in the morning, which is generally the case, the treatment ceases.

Under this treatment the acute symptoms subside after 48 hours, miction is easy, congestion has diminished, and pain has almost disappeared. Towards the fifth day the running is reduced to a drop in the morning, but otherwise, if three hours after micturition, a drop of pus is observed to ooze out, the abortive treatment has failed, and the malady will likely run its course of six weeks.

The chief feature of this treatment lies in the multiplicity of the injections with a weak antiseptic solution. No internal treatment is necessary.

Out of 27 patients treated by Dr. Carle, 22 were definitely cured.

PERUVIAN BALSAM.

The value, as an excellent and easy dressing for wounds of all kinds, of Peruvian balsam seems to be recognised by many surgeons on the Continent. In one hospital, all recent accidental wounds have been treated systematically for the last two years with this substance. After carefully removing from the wounds all extraneous matter, the dressing is applied and not repeated for a few days.

Of 25 complicated fractures, thus treated, there was but one death from traumatic pneumonia; the remainder recovered without difficulty. Traumatisms of the hand and the foot with open fractures, gunshot wounds, wounds of every kind, in fact, were treated successfully by the balsam. Tetanos was only observed three times out of 552 cases.

HYPERÆMIA OF THE PHARYNX.

Hyperæmia of the pharynx is a symptom of either nephritis or diabetes when no other has as yet existed. Sometimes it appears a little before either sugar or albumin can be detected. But there is no means as yet of knowing to which of these maladies the symptom will belong. Local treatment avails nothing; the general condition of the patient should be treated. The patient should be kept under observation, and put on a diet special to either of these maladies; abstention from sugar and a milk diet ordered. If it turns out to be a case of Bright's disease the milk régime will be made absolute; if it is one of diabetes the patient will be allowed milk and Vichy water, and the usual remedies prescribed.

GERMANY.

Berlin, Oct. 6th, 1907.

THE seventy-ninth meeting of the Naturalists' Society was held in Dresden from September 15th to the 21st, Professor Naunyn in the chair.

After the transaction of the customary formal business, the report of the commission of inquiry into the state of education was received. Professors Gutzmer, of Halle, and Klein, of Göttingen, were entrusted with the drawing up of the report. The Commission issued a series of questions respecting scientific education to the higher teaching institutions in Prussia. It appears from the answers received that 77 per cent. of the higher schools were in favour of practical physical school exercises. Practical chemistry was taught in most of the Realschulen, and ought to be generally. The equipment for teaching the natural sciences was, however, at present inconsiderable. A central depôt for the furnishing of physical apparatus was not indicated, but a museum of natural science-teaching material was very desirable. Students should be insured against accidents in experimenting and excursions. The Commission should now be dissolved and replaced by a general committee of education. The Government were in general inclined to reforms. The necessity of biological instruction in the higher classes of the advanced schools was recognised. Teachers should not be called upon to teach in subjects in which they had no practical knowledge. Education in the University ought to be purely scientific, and by no means limited to one object (should be Kein blosses Zweckstudium).

The first scientific general address was by Prof. W. Hempel, and had for its subject "The Treatment of Milk." He pleaded for increased prices in order that the agriculturist might be able to supply an immaculate milk. Mothers' milk was unreplaceable, and at present success had not be obtained in the destruction of the bacteria of decomposition and of the bacilli of tubercle, and for this reason he was in favour of getting the milk of the healthiest possible cows in the cleanest possible manner and using it unboiled, or raw. Cows are best kept on the land, and we ought to try to get the milk forwarded in cooled vans. Only animals that did not react to tuberculosis and showed no signs of other disease should be made use of for the supply of milk.

Prof. Kelling, Dresden, gave a report on his biochemical blood-serum examinations, and recommended that in giving the injections of blood, as Bier had suggested, for carcinoma, the blood should be specialised, that was, those kinds of blood should be used that were furnished by animals against which the bodies of the tumour patients were known to react, and the injections should be used in the first instance for the purpose of producing immunity against recurrences.

Prof. Eber, Leipsic, spoke on the importance of Behring's

TUBERCULOSIS IMMUNISATION PROCESS

for combating bovine tuberculosis. He was of opinion that the resisting power of young animals against artificial infection with virulent tuberculous material could be not inconsiderably heightened by preliminary treatment with tubercle bacilli of the most varied sources, but that this heightened power was not of long duration. There was as yet no proof that Behring's bovovaccination protected against natural tuberculous infection. Nothing had been published so far to show that any other method of combating bovine tuberculosis was superior to Behring's original protective inoculation.

Prof. A. Kuttner reported on 230 cases of

LARYNGEAL TUBERCULOSIS IN PREGNANCY.

In 12, artificial abortion was necessary, and in 9 it was successful, but in failed in 3. The result was favourable, however, in 7 only. In 15 cases tracheotomy or a similar operation was performed, but in only 4 with success; 200 of the women died either before delivery or shortly afterwards. Of 116 children 79 died. In the discussion that followed the paper, the opinion seemed to prevail that women with laryngeal phthisis who became pregnant should be warned of the great danger they ran on account of the pregnancy. Abortion should be induced if the tuberculosis showed a tendency to spread. In the latter months of pregnancy artificial interruption of it always had an unfavourable termination.

AUSTRIA.

Vienna, Oct. 6th, 1907.

LYMPHATIC LEUCOCYTHEMIA.

KIENBOCK exhibited to the "Gesellschaft für Innere Medicin" a male, æt. 47, from Constantinople, who was a business man in that city, and who suffered from a severe form of lymphatic leucocythemia. He consulted the doctor on December 19th, 1904. He had then large lymphatics the size of plums, besides packets the size of nuts. The spleen was 5 centimetres or two inches below the margin of the ribs, erythrocytes 5,100,000, hæmoglobin 14.9, leucocytes 185,000, of which 90 per cent. were lymphocytes, while the polynuclear neutrophile leucocytes were 3.5 per cent.

The patient was irradiated at intervals of two and three months, the application lasting 8 to 14 days at a time. The whole body was exposed at first, but finally only the spleen and glands. The doses were small throughout, not exceeding 2 to 4 quantimetric units. The effects of the X-rays on the spleen and glands were notable and rapid; they became decidedly less within two or three days. The leucocytes fell to average between 20,000 and 50,000. At the beginning of the treatment it might be stated a temporary rise took place, but soon fell again—the lymphocytes taking the greatest part in this increase, while the polynuclear leucocytes constantly decreased. The erythrocytes and hæmoglobins gradually fell, the former from 5 million to 4 million, and the latter in the same proportion—no granular red corpuscles could be observed in the examination.

For two and a half years the patient has had intermitting applications, but from the very beginning he felt stronger and better fitted for his business than he had for a long time prior to the commencement of the treatment. It is now four months since he was irradiated, but he felt well, although the glands were still slightly swollen as well as the spleen, and could be felt below the ribs by causing a deep inspiration.

The erythrocytes are now 4,000,000, and the leucocytes 18,000.

OBLITERATION OF AORTA.

Schrötter presented an interesting case of obliteration of the aorta at the arch or the ductus Botalli or Botalli region, as Hyrtl prefers to call it, having first been described by Dr. Botal, of Venice. The boy was ten years old, with the jugulars pulsating; this could be seen at a distance and corresponded to the carotid and subclavian. The arteries of the legs were better felt than seen, but no pulsation could be detected in the crural region.

The ductus Botalli is a relict of the embryonic form which in this case seems to have persisted and retained the collateral circulation through the arteria thoracica longa and intercostals which were greatly enlarged as well as the epigastric artery, which was almost free from convolutions in its function of descending aorta. One of the peculiarities of the case was the absence of palpitation!

MONGOLOID IDIOCY.

Friedjung presented a girl, æt. 16½, with that form of idiocy known as Mongoloid. Her external appearance had the characteristic symptoms: Small stature and stunted development. The face was short, suffused with a constant simper, forehead low, temporal bones depressed, and eyes with the Mongolian characteristics—distinct epicanthus and blepharitis. The mouth and nose were small, while the tongue was large, somewhat bifurcated. The cheeks were high and red, the ears small, and the jaws normal, the thyroid was normal to the feel, the speech explosive, confined to short phrases. Both hands were large, cold, and distinctly cyanotic.

Radical Cure of Hernia.

Bernhard has performed the most radical cure for hernia we have yet heard of. He practised the operation on dogs with perfect success. and has now performed with equally good results on man. The difficulty hitherto is the presence of the spermatic cord in the inguinal canal. Bernhard obviates this difficulty by separating the testis from the scrotum, and throwing it back into the abdomen, thereafter, entirely closing the ring.

Castration has always been considered too severe. This abdominal position preserves the physiological function, and provides an effectual means of closing the ring. The question arises: What will be the result if the testis become diseased and tuberculous or syphilitic inflammation arise? To avoid this, as a prophylactic, Bernhard splits the tunical vaginalis propria, which prevents hydrocele.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE PROBLEM OF THE INSANE.

In the eightieth annual report to hand of Murray's Royal Asylum, Perth, the Physician Superintendent, Dr. Urquhart, takes occasion to review the experience of a quarter of a century and to mention certain conclusions arrived at. The position of affairs regarding mental disease is that we have to deal with a constitutional malady, profoundly affecting bodily nutrition and secretion, mainly originating in hereditary defect, and issuing in a liability to repeated attacks of insanity. This generalized disorder (whether toxic by impairment of the bodily processes, or by bacterial invasion) brings the manifestations of mental disorder into line with other diseased bodily conditions, and leaves the mystery of madness on a par with the mystery of rheumatism, which is also of a cyclic character, quite different from those maladies which, like smallpox, appear to confer a future immunity upon the individual. All insanity is a defect—at least, a degradation of function, if not a degradation of structure. It is a mental reduction, characterised by a loss of the finer feelings, an inability to adapt, a loss of restraint on motor manifestations. The evidence for these opinions is rapidly accumulating. Never before have scientific observations been so numerous and so important relative to the study of insanity. These have become so wide and so intimately connected with all the ramifications of physiology and pathology, that it is difficult to keep pace with them; but if all the apparatus of our hospitals for the insane is not bent to the elucidation and treatment of bodily disease, they are *pro tanto* failures, obvious and indefensible. The general summary of results from 1880 to 1904 inclusive, shows that 982 patients were admitted—809 for the first time, and 173 as re-admissions. Of 809 persons admitted, 31 per cent. recovered, 39 per cent. were removed unrecovered, 17 per cent. died, and 12 per cent. remained resident. The results for cases (admissions or re-admissions) are nearly the same. The incidence of neuropathic heredity in these 809 persons is represented by 45 per cent. of hereditary insane, and 72 per cent. of hereditary neuropathy—*i.e.*, with family tendencies towards the graver neuroses, want of mental balance, alcoholism, and paralysis. An examination of the families of insane parents, however, showed that 47 per cent. of the children of insane fathers were alive and sane, while 29 per cent. were insane; 42 per cent. of the children of insane mothers were alive and sane, while 39 per cent. were insane; 33 per cent. of the children of insane fathers and mothers (both parents) were alive and sane, while 44 per cent. were insane. This morbid heredity falls heaviest on the eldest child, and rapidly diminishes with the number of children. There is, even in the most disastrous class, an effort towards regeneration, and a curability which does not greatly differ from that of insanity which is not hereditary in the first instance, although hereditary defect is apparent in depressing the final recovery rate, and raising the death-rate. Brief reference is also made to the effect of alcoholism, as there are so many misunderstandings and misrepresentations on that subject. A hundred and ten cases of chronic alcoholism were recorded among certified and voluntary patients. The total neuropathic hereditary amounted to 70 per cent.; nearly 43 per cent .were hereditarily predisposed to insanity, and nearly 22 per cent. to alcoholism. There is no doubt that the alcoholic patients received into asylums are generally and heavily burdened with a morbid heredity, and that their failure is analogous to that of the ordinary insane—a failure inherent in the organism, often made more manifest by environment. Mental stress is often alleged as the cause of intemperance, as the cause of insanity; the inevitable complement of the mental stress, however, is innate or congenital defect.

Turning to the statistics for the year, we note the high average of admission (45.8, as against 44.5 in 1906). There is also a large proportion of senile cases. The average age at the first attack of insanity, however, was 39.3 years. The general recovery rate of the asylum for the years 1865-1906 is 35.17; this year it is 27.02 (compared with 42.85 last year) on the number of admissions. The percentage of deaths was 6.72, the average rate of the institution being 6.17. The average daily numbers on the register were: males 71, females 63. The general health of the patients and staff has been good, except for an epidemic of diarrhœa in summer, and of influenza in spring.

The Reports of the Commissioners speak in high terms of the efficiency of the institution.

BELFAST.

The Corporation and the Treatment of Consumption.—At the last meeting of the Public Health Committee the draft agreement between the Forster Green Hospital for Consumption and the Corporation was read. The hospital is to provide and reserve twenty-five beds similar to the existing beds in the hospital for the sole and exclusive use of patients to be nominated by the Public Health Committee, and approved. The agreement is to continue for ten years, during which the Corporation shall pay to the hospital the sum of £2,275 annually. The Lord Mayor for the time being, the Chairman for the time being of the Public Health Committee, and two other persons as the said committee shall appoint, shall be members of the Hospital Board. The working of this arrangement will be looked on with great interest, as certain difficulties are obvious.

Tuberculosis Exhibition.—A meeting was held in the City Hall on the 1st instant, the Lord Mayor (the Earl of Shaftesbury) presiding, to make arrangements for a Tuberculosis Exhibition in Belfast. Sir John Byers, Professor Lindsay, Dr. Dempsey, and other medical men took part, and Drs. Thomas Houston and J. McIlwaine were appointed honorary secretaries.

Banbridge Nursing Society.—The annual meeting of this society was held in Banbridge, co. Down, last week, and the report read showed the usual busy year's work which one has learned to associate with district nursing societies. But it contained one item of interest to medical men which such reports do not generally give; it gave the number of cases sent to the nurse in different ways. Of a total of 119 patients, 81 were recommended by friends, 21 by doctors, 5 by clergymen, and 12 by members of committee. This looks as though the services of the nurse were not so often utilised by the local medical men as might be the case.

LETTERS TO THE EDITOR.

PROTECTION FOR BEAST, NOT FOR MAN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Years ago, and on numerous occasions since, you have allowed me to point to and discuss, when called for, the fact that the Veterinary Act affords greater protection to the profession and the public than the Medical Acts. This is exemplified once more by a case reported this week. At Feltham Petty Sessions, on September 30th, a man was summoned for using the description, "canine and feline medical expert," implying that he was specially qualified to practise a branch of veterinary surgery. Although the man was ably defended, and it was not proved that he had actually suggested to his clients that he was a veterinary surgeon, he was convicted and fined 20s. Under the Medical Acts such a conviction is at present impossible, and there exists no functionary or public body like the Veterinary College, charged with enforcement of the law, even if it were applicable. Whether guilty of no greater real harm than the man in the present case, or carrying on the grossest system of cruel quackery and extortion, the unqualified medical practitioner cannot be prevented from palming himself off as a duly qualified man. He can employ language in his advertisements capable of deceiving not only the ignorant but the educated public, and there are hundreds of such men carrying on their nefarious trade throughout the country. It is impossible to believe that the Legislature would allow this state of things to continue if once the facts were forced to the knowledge of responsible men and statesmen. It needs no elaborate proof to show that it is at least as important to protect suffering humanity as suffering brutes against the injury which ignorance, incompetence, and dishonesty can inflict upon them. It is, I hold, the duty of the profession to take up and force to the front the question of medical law reform. As a preliminary step the case for legislation must be made out clearly and beyond dispute; and as nearly the whole of the newspaper Press, high and low, is suborned in support of quackery, this can be done only by means of an authoritative inquiry such as, I believe, would be afforded by a Royal Commission.

I am, Sir, yours truly,
HENRY SEWILL.

Cavendish Square, October 1, 1907.

A NEW ERA IN MEDICINE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the *Times* of October 1st there appears a remarkable article under the above heading. It is printed in the form of editorial matter, and I do not know whether the editor is responsible for it, or whether it is, after all, merely a paid advertisement. The sub-heading refers to a "Remarkable address at the opening in London of a West-end home of a famous Continental spa cure," but not a word of any address is to be found in the article. According to its promoters, this so-called "St. George's Nauheim Institute has been founded to meet the demand for progress by both patient and physician," but who the patient is, and especially who the physician, the article does not tell. We are, however, told that readers of the *Times* who want to know may learn all about it by applying at the Institute for a copy of the "handsome opening Souvenir Book," a work which we are further informed "must prove of vital import to readers who have personal reasons for desiring acquaintance with the latest methods that mark this new era in medicine." If your reporter was not present at the opening ceremony, I trust that one of your ablest representatives will be at once despatched, so that your readers may not remain long in suspense before they are enabled to take advantage of "the new era in medicine," and pass on their knowledge for the benefit of their patients.

I am, Sir, yours truly,
RUSTICUS.

October 3rd, 1907.

[*** The article referred to by our correspondent has appeared in several newspapers besides the *Times*. Although typed as editorial material, it is a cleverly concocted advertisement, and is paid for as such.—ED. M. P. AND C.]

CONGENITAL ANOMALIES OF THE EYE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I point out a mistake in Mr. Sydney Stephenson's very interesting lecture on "Congenital Anomalies of the Eye," in your issue for September 25th? On p. 331 he says:—"I note that the latest book on Diseases of the Eye, by Mr. J. Herbert Parsons, contains the caution not to diagnose pseudo-neuritis 'unless at least 2 D of swelling can be demonstrated.'" If he will refer again to the quotation, he will find that the actual words are:—"*Papillitis* should not be diagnosed unless at least 2 D of swelling can be demonstrated"—exactly the opposite of the deduction which he has drawn. The sentence would doubtless have been less ambiguous and more accurate if I had said that "Papillitis, in the absence of other definite signs, such as hæmorrhages, exudates, etc., should not . . ." I quite agree with Mr. Stephenson in thinking that there is probably never abnormal swelling of the disc in pseudo-neuritis.

I am, Sir, yours truly,
J. HERBERT PARSONS.

27, Wimpole Street, Cavendish Square, W.,
September 26th, 1907.

"THE INTRODUCTORIES."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is to be wondered what most of your readers thought of the Introductories. These effusions certainly were not very cheerful in their tone, that is, encouraging to the young freshmen. Dr. Allchin warned his hearers against the London University. Dr. Ewart certainly took the view that the life of a general practitioner is a miserable one, and in any case a man without means had better keep clear of doctoring, so far as making a living out of practice could be relied on. The other lectures were more or less special, except Dr. Osler's, and he soared into the regions of sentiment and high morality. One subject might have been dealt with, but it was carefully avoided, and that is the influence of unlimited hospital treatment upon the great body of general practitioners, and the extent to which they have suffered. This, of course, is a subject the hospital man dare not deal with, and it would be well if it were boldly considered by the readers of your journal and by the great body of general practitioners throughout the country.

Yours truly,
A REFORMER.

THE NOTIFICATION OF BIRTHS BILL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I have not the leisure to deal with Dr. McWalter's article in any detail which appears in your last issue, nor do I really think it worth while. I do not believe that medical men will subscribe to the ideas contained in the words as I have heard them expressed, "let the poor little devils die." But I would point out that the mere title of the article ("The Government's Scheme to Promote the Unqualified Practice of Medicine") is at once a libel on the promoters of the Act, an untruth, and an appeal to vulgar passions. It is a libel on the promoters of the Act because they were single-minded in their object; *one thing only* they had in view, namely, to save the lives of helpless babies who are being slain in appalling numbers year by year in this country by the inertia and apathy of the responsible governments, central and local, of the country. The title is an untruth on the face of it. It is ridiculous because it is so obviously untrue. It is just as difficult to point out how it is untrue as it is to give an algebraical demonstration that two and two make four. And it is an appeal to vulgar passions because it ignores the highest and best traditions of our profession, while appealing speciously and meretriciously to self interests.

The Government's Act arises from and follows the lines of the Huddersfield Act, which originated with me. I, therefore, am able to speak with some authority. I trust that it is hardly necessary for me, a medical man, to assure my fellow medical men that I have no desire, and never have had the least desire, to promote the unqualified practice of medicine. In Huddersfield the working of the Act cannot possibly promote the unqualified practice of medicine, because it is worked by two duly qualified and legally registered medical women, *as I have stated in Dr. McWalter's presence.*

Faithfully yours,
J. Moore,
Medical Officer of Health.

OBITUARY.

DR. ARTHUR C. HUDSON, J.P.

We regret to have to record the death of Dr. Arthur Hudson, who died at his residence, near Avoca, in co. Wicklow, at the age of 71. Dr. Hudson acted as medical officer in Avoca for 48 years, and was said to be the oldest dispensary medical officer in Ireland. He was well-known throughout Wicklow, and for the last twenty years was a regular attendant at the local Petty Sessions in his capacity of Justice of the Peace.

REVIEWS OF BOOKS.

BUCHANAN'S MANUAL OF ANATOMY. (a)

Some months ago, when reviewing the first volume of this manual, we were struck by the success with which the author, Professor Buchanan, had combined a systematic and practical Anatomy in one text-book of convenient size. In it the student, when dissecting the extremities, can refer to the description and figures of the bones in the part of the work devoted to osteology. At the same time he has a guide to the method and procedure of dissection following the description of each completed part, and can acquire a sound knowledge of the subject without referring to any other book. The advantages of this arrangement in the manual will at once recommend itself to the teacher as well as the student.

In Volume II., now before us, we find the same admirable plan of treatment of the subject is employed. The reader is given every facility to grasp not only the gross anatomical details but also at the same time can make himself familiar with the developmental history and the histology of the organ which he meets with. The structure of each viscus is fully described. For instance, in the kidney, the relative position, size, shape, lining, epithelium and lumen of the uriniferous tubules are clearly dealt with, and the minute details of the blood supply are given. The present Volume II. is nearly twice the size of Volume I. About the first 300 pages are devoted to the abdomen, 64 of which deal with the structure and development of the abdominal and pelvic viscera. The next 200 pages treat of the thorax. The development of the heart and great blood vessels, and the fœtal circulation, are described at considerable length. The anatomy of the head and neck, the nervous system, the nose, eye, and ear occupy the next 500 pages. An Appendix contains the Bâle nomenclature and a glossary. The latter particularly will be appreciated by the beginner.

Vol. II. is particularly well illustrated (363 figures). Many of these are coloured, especially in the section dealing with the nervous system, where the various nerve tracts are picked out in different tints. The illustrations and diagrams of the microscopic sections leave nothing to be desired. There are also numerous figures devoted to embryology. The only regret we have in regard to this manual is that Professor Buchanan has not included a brief general account of the development of the embryo to aid the student in elucidating particular details.

In conclusion, the many obvious merits of Buchanan's work will rapidly ensure its becoming one of the most popular text-books of the dissecting-room. In it the examination requirements of the student are kept constantly in view, and the subject of human anatomy is made interesting, clear and comprehensive.

TREATMENT OF HIP DISEASE. (a)

This monograph is based upon the author's large experience in the treatment of hip joint disease. He follows very closely the methods advocated long ago by Thomas, but greatly improved on by the author himself. After defining what is meant by hip disease and referring to its pathology, the writer goes on to speak of rest in the treatment of the inflamed joint. Rest is to be obtained by the use of a Thomas's splint. He then specifies in detail the apparatus required for measuring in an ordinary typical case. His method is an improvement on Thomas's, and gives a certainty of fitting the splint to the patient with far greater accuracy and celerity. The directions given are so minute and explicit that anyone can readily understand and carry them out.

The method of making the required splint is next given, and the apparatus required for fitting the splint is fully described and illustrated. The results obtained by the author have been uniformly successful, and certainly his suggestions are excellent in theory. Having referred to the treatment of ordinary and recent cases with flexion and little or no lateral or rotatory displacement, the writer then goes on to speak of the treatment of some complications and sequelæ, especially of cases of old-standing with great deformity. Those cases, he says, in which the limb is fixed in extreme flexion can be reduced by treating them with a double Thomas's splint, made in the same way as a single one with two upright stems, set parallel and at a distance of one inch more than the distance between the tip of the right and the left posterior superior spines.

Prophylactic and drug treatment is also referred to, as well as the operative forms of interference which may be required in very advanced cases of this disease. Regarding bloodless surgery Bennie says that it is "bad surgery, and is a most dangerous operation. Although this operation has been called bloodless surgery, it is usually a most bloody one, but you do not see the blood; it is effused from the torn structures covered by the skin. It is more likely to aggravate than ameliorate the condition." The work is completed by a suitable account of cases actually treated by the author on the lines laid down by him. We have read this monograph with considerable interest as it bears the evidences of much originality of thought, and shows that the writer knows well his subject. It is a book with which every surgeon should make himself thoroughly familiar.

INTERNATIONAL CLINICS. (a)

Volume I. of this quarterly contains the usual yearly summary of the progress of therapeutics, medicine, and surgery, in addition to a series of clinical lectures on various medical and surgical subjects. The individual papers are 14 in number, and are well selected. Dr. Walsh, of New York, writes a most valuable and practical article on the treatment of functional heart disease; Dr. Warthin writes on "The

(a) "International Clinics." Vols. I. and II. Seventeenth Series. Philadelphia and London; J. B. Lippincott Co. 1907.

Clinical Diagnosis of Enlargement of the Thymus"; Dr. Morton on "Neurotic Affections of the Joints"; and an elaborate article on "Disorders of the Umbilicus" is contributed by Gallant. These, to our mind, are the pick of the lot, but the remaining ones are useful as able clinical expositions of the treatment and diagnosis of many of the every-day conditions encountered in general practice. The chief value, indeed, of this journal depends, we think, on its method of dealing throughout the year with common conditions, and laying before the practitioner succinct and up-to-date accounts of what he is constantly being called upon to treat and diagnose. That its method is appreciated is proved by the place that it continues to occupy in medical journalism.

For several years we have been accustomed to say that the annual summary found in the International Clinics is the most readable and useful of the numerous digests of medical progress that are published. This year's summary bears out that opinion. It occupies a little over 100 pages, and yet a careful perusal of it convinces us that nothing of importance has been omitted. At the same time the writers seem to have made a most careful selection, and to have eliminated the great bulk of useless writing that yearly crowds the journals and wearies the reader. The very brevity of the summary enhances its value, for a mere glance enables one to gain possession of the salient points that have engaged medical thought and investigation throughout the year. As usual, the surgical summary is somewhat better than the medical one, because it is written in a narrative style and does not attempt to summarise all surgery, but only to deal with the more advancing branches of the science. Some parts of this section are well illustrated.

Amongst the papers in Volume II. is an interesting one by Flexner on "Experimental Cerebro-Spinal Meningitis," in which he summarises the results of his experiments as published elsewhere. He points out that in periods of from 14 hours up to two or three days after injection by lumbar puncture of cultures of the diplococcus intracellularis into the spinal canal of monkeys, an inflammatory reaction is produced which resembles the condition found in epidemic cerebrospinal meningitis in man. In most of the monkeys, moreover, the nasal mucosa becomes inflamed, and although the organism has not been cultivated from the nose, still diplococci resembling it have been seen in the polynuclear cells of the nasal exudate. This work seems to foreshadow the possibility of the production of an anti-serum for the disease. Two other interesting pathological papers appear, one an admirable summary of our knowledge concerning the macroscopic and microscopic characters of normal and abnormal bone-marrow; the other a contribution to the pathology of general infection by the gonococcus. In the Gynæcological Section Cuthbert Lockyer writes an instructive article on "Appendicitis in Pregnancy," and gives an account of six cases of his own. Clogg writes on "Perforated Duodenal Ulcer," discussing principally the diagnosis and treatment of this condition, and pointing out its comparative frequency. Numerous other papers of interest to both the specialist and the practitioner are included, but are too numerous for individual mention. Many will welcome the opening paper of the Therapeutical Section. It contains a simple and sufficient statement of the theory and principle of vaccine treatment in infectious diseases.

AUSCULTATION AND PERCUSSION. (*a*)

THE majority of students, it is to be feared, do not make a study of physical signs as elicited by auscultation and percussion, contenting themselves with the more or less perfunctory instruction they receive in the wards and out-patient rooms, so that they fail to grasp the *rationale* of the methods they employ, and, memory failing, their powers of observation are left unnecessarily limited. Yet on their ability to apply and interpret correctly the methods of acoustic investigation depends their skill as diagnosticians in a whole series of grave affections. Carelessness, or want of method, or ignorance may render the observer blind to the most obvious phenomena, to the detriment of his reputation and to his ability as a practitioner of the healing art.

A well-thought-out work like the one before us provides the student—and, if need be, the neo-practitioner—with the means of co-ordinating his knowledge and experience, and enables him to reason out that which he may fail to remember. Of the work itself it is hardly necessary to speak, seeing that it is by this time a standard treatise on the subject, couched in language which, if at times a shade archaic, is unusually choice for a technical work.

The history of the subject, as well as the subject itself, is peculiarly interesting. How signs so obvious could have escaped the keen observation of our professional progenitors must ever remain a matter for surprise; but in all probability they had a better acquaintance with them than we are apt to believe.

The author is well advised to impress his readers with the fact that there are other senses than that of hearing, and that the stethoscope does not exhaust our means of perception or dispense with the necessity or other modes of investigation—in other words, auscultation and percussion do not cover the whole field of clinical exploration.

Admirably printed and neatly bound, the work is one to figure in every medical library. It will well repay attentive study.

THE DIGESTIVE SYSTEM. (*a*)

IT is often said nowadays that the surgeon is leaving little or no field for the pure physician, but a book of this kind tells another tale. At the same time it remains true that much of the diagnosis ends in surgery, and the American translator is careful to point out that many of the diseases included lie on the borderland of medicine and surgery. The present work is of considerable value, inasmuch as it presents in English form a careful and authoritative translation of the well-known work, "Die Deutsche Klinik," issued under the editorial supervision of Dr. Julius Salinger. The list of 21 contributors includes the names of many leading Continental authorities. Among them may be mentioned Rosenheim, Ewald, Hirschfeld, Strauss, Boas, and Statelmann, of Berlin; Neisser and Nothnagel, of Vienna; Hoppe and Seyler, of Kiel; Suanboyle, of Bonn; and Fleiner, of Heidelburg. The section upon gallstones, by Neisser, is particularly full and interesting, and that upon gastric ulcer and gastric hæmorrhage compact and accurate. There are 45 illustrations of good quality. The book has been carefully edited, and Professor Billings may be congratulated on presenting to English readers a book that will be invaluable to all physicians.

ON POLYPUS. (*a*)

THE subject under consideration in this monograph has been much debated and many divergent theories have been advanced, so that a concise work of real value is needed in collecting the views of many different authors and at the same time giving those of the writer. The following theories are worthy of mention:—1. That polypi are true tumours. 2. That polypi are peculiarly modified granulations. 3. That polypi are almost invariably a symptom of suppuration in the accessory sinuses of the nose. 4. That polypi are merely a symptom of disease of the ethmoid bone. 5. That polypi are œdematous hypertrophies of the nasal mucous membrane, the indirect result of certain mechanical changes in the mucous membrane glands. The writer's own theory is stated in the words above under the heading 5, and he sums up his remarks as follows:—

1. Chronic inflammation of the mucous membrane.
2. Dilatation of the glands going on to cystic distension, caused either (*a*) through marked inflammatory infiltration of their ducts produced by septic

(a) Polypus of the Nose." By Eugene S. Yonge, M.D. Manchester Sherratt and Hughes.

discharges, or (*b*) through excessive filling of the gland combined with a partial obstruction to the exit of the gland contents.

3. Œdematous infiltration of the surrounding tissues, resulting from the passage of serum through the capilliary walls, due (*a*) to increased pressure in certain capilliaries, owing to obstruction of the capillaries into which they lead, (*b*) to increased permeability in the capillary walls, the result of inflammation, and (*c*) to the laxity of the surrounding tissues.

4. The formation of folds or projections on the infiltrated mucous membrane.

5. The increase of œdema in certain of the folds, formed in the manner described, combined later with a hyperplasia of the fibrous elements.

6. The formation of flat œdematous structures containing the essential constituents of the nasal mucous membrane (broad based or sessile polypi), or of œdematous structures containing the same constituents but a greater amount of fluid, and perhaps of hyperplastic tissue, and each possessing a base which gradually becomes relatively constricted and stretched, until it constitutes a pedicle. This connects the remainder of the structure—which now, through the influence of gravity and other physical causes, has become a globular swelling (pedunculated polypus)—with the mucous membrane from which it sprang.

The little book adds to our knowledge of the subject and is worthy of careful study.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

Sidney Appleton (London).
Minor Medicine: A Treatise on the Nature and Treatment of Common Ailments. By Walter Essex Wynter, M.D., etc. Pp. 275. Price 6s. net.

Bailliere, Tindall and Cox (London).
Bloodstains: Their Detection and the Determination of their Source. By Major W. D. Sutherland, I.M.S. Illustrated. Pp. 167. Price 10s. 6d. net.
Treatment by Hypnotism and Suggestion. By C. Lloyd Tuckey, M.D. Aberdeen. Fifth Edition. Revised and Enlarged. Pp. 418. Price 10s. 6d. net.
Nature's Hygiene and Sanitary Chemistry. By C. T. Kingzett, F.I.C., F.C.S. Fifth Edition. Pp. 527. Price 7s. 6d. net.
Marine Climates in Tuberculosis. By William Ewart, M.D., etc., etc. Pp. 48. Price 1s. net.
Preventable Blindness. By N. Bishop Harman, M.A., M.B. Cantab., F.R.C.S.Eng. Illustrated. Pp. 109. Price 2s. 6d. net.

MEDICAL NEWS IN BRIEF.

London Medical Exhibition.

The third London Medical Exhibition, organised by the "British and Colonial Druggist," was opened on Monday at the Royal Horticultural Hall, Westminster. Compared with last year the exhibition marks a great advance; not only is every inch of space taken up, but the interest upon the part of the medical profession is greater than in the previous two years. Last year close upon 5,000 medical men within a radius of twenty miles from Charing Cross visited the exhibition. Patent and special foods and beverages are in great variety. "Equipoise, Limited," exhibit samples of furniture which are as much sought after by the ordinary person as the invalid. Beds, mattresses, chairs, and other articles are in profusion, among others a replica of a couch which was specially ordered by the Queen, and is now in use at Buckingham Palace. The Hospitals and General Contracts Company have an interesting show of their aseptic furniture. The Aylesbury Dairy Company explain what can be done to ensure pure milk. Parke, Davis, and Co., among many other useful exhibits, have a speciality in the shape of the "Yachtomobile" first aid case. As its name indicates, it is suitable either for yachtsmen or motorists, and contains everything necessary to render first-aid in cases of emergency, accident, or shock either on a yacht or motor-car. Messrs. Hearon, Squire, and Francis have on view many samples of opium. These include Persian, Chinese, and English—the latter being most rare and produced in Lincolnshire. They are shown in the raw condition, and also made up in the form of tabloids, although for the English product it should be said that it is probably the only sample of its kind to be found in this country. The exhibition remains open until Friday.

Sanatorium for Consumptive Children.

THE first British sanatorium for consumptive children was opened on October 4th, at Stannington, by the Duke of Northumberland. The institution is in the care of the Poor Children's Holiday Association, which, managed by Mr. J. H. Watson, of Sidney Grove, Newcastle, is accomplishing a work that is deserving of much praise. The Association was started in the year 1891, by taking some of the little slum-dwellers to the seaside; and now it has a training home for girls, a convalescent home, boys' rescue and labour homes, and innumerable agencies for the betterment of the poor street children. At Stannington there is a convalescent home and a farm colony, and a sanatorium in which consumptive children have every chance of being restored to health. Mr. Watson's projects have good friends, who appreciate the enormous value of his labours; but the Association needs £2,000 to complete the capital cost, and, for the expansion of the farm colony, £1,000 is required for a new field. The sanatorium will require at least £3,000 per annum to carry out its work. Boards of Guardians and other bodies have talked about the provision of sanatoria for consumptives; but, if they would endow beds in such an institution as that at Stannington, they would find the work well done, and save the cost of erecting special buildings. The parents of the children contribute towards their support, where they can. But most of the lads upon the farms are orphans

Sheffield Midwife.

AN inquest was held on October 5th at the Jessop Hospital, Sheffield, relative to the death of a woman who had died from puerperal fever. The deceased woman was the wife of a plumber. The inquest was conducted by the City Coroner. According to the evidence of the husband a midwife, Mrs. Fetch, attended the deceased on Friday, September 20th, and the following five days, but did not visit her on the 26th until fetched. Deceased was then in a very bad state, and on the following day was removed to the Jessop Hospital, suffering from puerperal fever. She died there on October 2nd. It was suggested that the midwife had not treated deceased properly, and that a doctor ought to have been sent for sooner. Elizabeth Fetch, the midwife, said she attended deceased at her confinement, which was a perfectly normal and healthy one. Deceased went on well till Thursday, and on that day witness was fetched. She went, and owing to the condition of her patient, told the husband to fetch the doctor, and he did so. She had never asked him to fetch one before, and he had never asked her to do so. She had, however, advised the deceased to have one the day before.—Coroner: But you said she went on all right up till Thursday. Why did you advise her to have one? Witness: She had pains in her head.—Then she did not go on all right? No, sir.—You advised her to have a doctor the day before? Yes, sir; but she refused. Witness contradicted herself several times whilst being cross-examined by Mr. Coath. Asked as to the number of days a midwife was supposed to attend a patient, she first said seven days in succession and the tenth day, and then ten successive days.—Mr. Coath: Did you ever take the temperature of this woman?—Witness: No.—Do you take the temperatures of your patients?—No; I don't understand the thermometer. Replying to further questions, witness first said she had not received complaints from the medical officer of health as to her treatment of patients, and afterwards admitted she had. She also said she could not remember the name of the disinfectant she was in the habit of using. After evidence had been given as to the cause of death, the jury returned a verdict to the effect that deceased had died from puerperal fever. They also added that they thought there had been considerable neglect on the part of the midwife, and that they did not think she was quite the proper woman to practise.

The Carbolic Co-efficients of Sanitas-Okol.

EXPERIMENTS have been made by Dr. Klein with "Sanitas-Okol" to ascertain its carbolic co-efficient on B. Typhosus (a) under ordinary conditions, *i.e.*, in watery dilutions, and (b) in the presence of organic matter—nutrient broth (beef broth and peptone). The strain of B. Typhosus tested was an active subculture in nutrient broth (24 hours' incubation at 37°C) derived originally from the spleen of a fatal case of enteric fever, several generations removed from the original source. In all instances to 5cc. of the dilutions of Phenol or "Sanitas-Okol" respectively five drops of the broth culture of B. Typhosus were added, and after exposure for the desired time, three loops—same loop being always used—were taken from the medicated fluid, and transferred to sterile nutrient broth in tubes. These were then transferred to an incubator, and kept for three days at 37°C, after which time the result was noted. From the experiments it appears that in the absence of organic matter the carbolic co-efficient of "Sanitas-Okol" is $\frac{1800+1700}{90+85}=20$; in the presence of organic matter it is $\frac{1600+1500}{90+85}=17.7$.

Death under an Anæsthetic.

MR. HENSLOWE WELLINGTON held an inquest on the body of Robert M'Donald, aged 47, a pastrycook, who died in St. Thomas's Hospital after undergoing an operation. Robert Greatorex, brother-in-law of the deceased, complained that the hospital authorities did not notify the relations that an operation was to be performed and that a relapse had followed. Dr. Nightingale, house surgeon at St. Thomas's Hospital, said that the deceased had called at the hospital some days before, and had been informed of the necessity for an operation, and came to the hospital on Monday for that purpose. He was asked to communicate to the relatives the fact that the operation was to be performed on the following day. He promised to do so, but apparently did not. The operation was a difficult one, and ether was the anæsthetic used. It was successfully completed, but later hæmorrhage started from the surgical wounds, and though all that was possible was done, the hæmorrhage continued. It was decided that nothing more could be done for him without an anæsthetic, and the deceased was taken to the operation theatre again. Chloroform was administered, and under its influence deceased stopped breathing. Artificial respiration was resorted to, and Mr. Adams, one of the surgeons, endeavoured to massage the heart, but it was found to be flaccid. In answer to the first witness the doctor said that the case was so urgent that there was no time to communicate with the relatives. Dr. Trevor said that death was due to heart failure due to loss of blood following on the operation. The jury returned a verdict accordingly.

Disputed £100,000 Hospital Bequest.

AN influential committee of ratepayers in Streatham have recently circulated a memorial to the Charity Commissioners with the view of obtaining £100,000 left by the late Mr. Weir to establish a medical institution in Streatham parish. The holders of the money, it is alleged, now propose to hand over practically the whole sum to the Bolingbroke Hospital, which is in the Borough of Battersea. The petition says that Streatham needs the hospital, and that they should not be deprived of the bequest given to them by the late Mr. Weir for the hospital and a properly organised ambulance service.

REUTER'S Agency has received from the chief medical officer of Helsingfors a statement that no cases of Asiatic cholera have occurred in that town. This declaration refers to a Reuter's telegram of September 18th stating that three cases of cholera had occurred at Helsingfors.

Pathology in Bristol.

Before the function at the opening of the winter session at University College, Bristol, when Professor Gotch distributed the prizes, and delivered a stirring address on the University question, Professor Walker Hall gave a demonstration in the Museum of the Royal Infirmary. This was largely attended by medical men from the districts around. At 2.30 p.m. there was a lantern demonstration of microscopical preparations. This was followed at 2.45 p.m. by an account of residual opsonins by Dr. J. H. Munro. Dr. J. J. Lucas related some anomalous cases of tuberculosis—cases which gave practically no clinical symptoms, or gave indications of typhoid, or of pernicious anæmia. Dr. Walker Hall then described some new methods for the mounting of museum specimens, and for the estimation of sugar in urine, and fat in fæces.

Entrance Scholarships at the London Hospitals.

The following announcements were made at the opening of the Winter Session at the London Medical Colleges:—

St. George's Hospital.—The University Entrance Scholarships in Science have been awarded as follows:—R. F. Jones, B.A., Pembroke College, Cambridge, and L. A. Lewis, Edinburgh University, equal, a scholarship of 60 guineas each, and E. W. M. H. Phillips, Jesus College, Oxford, scholarship of 50 guineas.

London Hospital.—Price Scholarship in Science, value £120.—Mr. T. D. Williams. Science Scholarships, value £60.—Mr. N. R. Rawson. Science Scholarships, value £35.—Mr. J. H. Lloyd. Price Scholarship in Anatomy and Physiology.—Mr. G. J. F. Jessel (Univ. of Oxford). Epsom Scholarship (£126).—Mr. E. H. Henson.

Charing Cross Hospital.—The following Entrance Scholarships have been awarded:—The Epsom Scholarship (115 guineas), to Mr. J. E. Ashby; The Huxley Scholarship (55 guineas), to Mr. E. M. Morris. Entrance Scholarships have also been awarded to Mr. A. E. Hallinan (40 guineas), and to Mr. W. Leslie (30 guineas). Universities Scholarships of 72 guineas each have been awarded to Mr. W. R. Thomas and Mr. C. W. Shepherd, both of the London University.

Middlesex Hospital.—The following Entrance Scholarships have been awarded:—Arts Scholarship.—Mr. C. E. Thornton. Science Scholarship.—Mr. W. Butterfield. University Scholarship.—Mr. W. M. Penny. Frere Lucas Scholarship.—Mr. A. L. H. Rackham.

King's College Hospital.—The following Scholarships have been awarded in the Faculty of Medicine:—Medical Entrance University Scholarship (£50).—H. A. Treadgold. Warneford Medical Scholarship (Arts) (£50).—A. S. Wakeley.

The Porthcoming Tuberculosis Exhibition in Ireland.

An inaugural address in connection with this exhibition will be delivered by Professor William Osler, F.R.S., Regius Professor of Medicine in the University of Oxford, in the Theatre of the Royal Dublin Society, Kildare Street, on Friday, October 11th, at 8.30 p.m. The title of the lecture is, "What the Public Can Do in the Fight Against Tuberculosis." Admission will be free.

PASS LISTS.

University of Durham.

At the Convocation held on Saturday, September 28th, 1907, the following degrees were conferred:—

Doctor in Medicine.—Thomas Hartigan, M.B., B.S., Durh.; Frederick William Kemp, M.B., B.S., Durh.; Wharram Henry Lamplough, M.B., B.S., Durh.; Frank Laughton-Smith, M.B., B.S., Durh.; Frederick Robert Henry Laverick, M.B., B.S., Durh.; Morgan Richards, M.B., B.S., Durh.; Ernest Charles Young, M.B., B.S., Durh.

Doctor in Medicine for practitioners of fifteen years' standing.—Henry T. S. Aveline, M.R.C.S., L.R.C.P.; Edgar Beaumont, M.R.C.S., L.R.C.P.; John F. Butler-Hogan, B.A., M.D. (Brux.), L.R.C.P. and S., L.F.P.S.G., D.P.H.; Geoffrey Cross, M.R.C.S., L.R.C.P., L.S.A.; John Cumming, F.R.C.P. and S., E., L.F.P.S.G.; Ludford Cooper, M.R.C.S., L.R.C.P.; John Freeman, M.R.C.S., L.R.C.P.; Arthur Hawkyard, L.R.C.P. and S., E.; John W. D. Hooper, L.R.C.P. and S.; Hedley Hill, M.R.C.S., L.R.C.P.; Llewellyn Lewis, M.R.C.S., L.R.C.P.; William M. Palmer, M.R.C.S., L.R.C.P., L.S.A.; Arthur W. Read, M.R.C.S., L.R.C.P., F.S.A.; Hugh J. Roberts, M.R.C.S., L.S.A.; Henry F. Steele, M.R.C.S., L.R.C.P., L.S.A.; John F. Woodyatt, M.R.C.S., L.R.C.P.; Richard M. West, M.R.C.S., L.R.C.P.; George C. W. Wright, M.R.C.S., L.R.C.P.

Bachelor in Medicine (M.B.).—George E. P. Davis, L.R.C.P. and S., L.F.P.S.G.; William H. Edgar; George R. Ellis; Charles W. Greene; Herbert F. Joynt; Edward P. Joynt; Charles G. Kemp, M.R.C.S., L.R.C.P.; Herbert Max Levinson; Hector G. G. Mackenzie, M.A.; Stanley D. Metcalfe; Elizabeth N. Niel; Roland W. Pearson, M.R.C.S., L.R.C.P.; James W. Smith; George Walker; Lionel L. Westrope, L.R.C.P. and S., L.F.P.S.G.; Frank Whitby; Cuthbert R. Wilkins.

Bachelor in Surgery (B.S.).—George Edward Peckett Davis, L.R.C.P. and S., L.F.P.S.G.; William H. Edgar; George R. Ellis; Charles W. Greene; Herbert F. Joynt; Edward P. Joynt; Charles G. Kemp, M.R.C.S., L.R.C.P.; Herbert Max Levinson; Stanley D. Metcalfe; Elizabeth N. Niel; James W. Smith; George Walker; Frank Whitby; Cuthbert R. Wilkins.

Bachelor in Hygiene (B.Hy.).—George Denholm, M.B., B.S., Durh.; George P. Harlan, M.D., Ch.B., Glas.

And the following received the Diploma in Public Health (D.P.H.).—George Denholm, M.B., B.S., Durh.; Albert G. W. Pearson, M.B., B.S., Durh.

Guy's Hospital Medical School.

The following Entrance Scholarships and Certificates have been awarded:—Senior Science Scholarships for University Students (£50): J. G. Saner, Caius College, Cambridge.

Junior Science Scholarships (£150): J. F. Mackenzie, Preliminary Scientific (M.B.) Class; (£60) R. D. Passey, Preliminary Scientific (M.B.) Class.

Certificates.—T. J. Bennett, Preliminary Scientific (M.B.) Class; G. E. Genge-Andrews, Preliminary Scientific (M.B.) Class; S. Keith, Preliminary Scientific (M.B.) Class.

Entrance Scholarships in Arts.—(£100) C. S. L. Roberts, Cheltenham College; (£25) G. D. Eccles, Plymouth Technical School and (£25) G. F. Romer, Malvern College (equal).

The Royal University of Ireland.—The Third Examination in Medicine.

The following candidates have passed the above-mentioned examination:—

Upper Pass.—*Albert V. Craig, *William Dickey, James A. Hanrahan, *Richard W. G. Hingston, David Horgan, *John C. Houston, *Edward G. Kennedy, Ernest W. Kirwan, *Patrick J. Lydon, B.A., *Michael G. O'Malley, David A. Rice, Thomas Scanlan, William S. R. Steven, Alfred M. Thomson, Michael Twohig. (Those marked with an asterisk had the liberty of presenting themselves for the further examination for Honours, which commenced on Monday morning, October 7th.)

Pass.—David R. Acheson, William J. Ashby, Percy M. J. Brett, Daniel Broderick, Francis S. Carson, Victor L. Connolly, William Doolin, Joseph S. Doyle, William P. Dunne, B.A., Patrick Hayes, Jeremiah Holland, Joshua Keyms, B.A., Samuel K. McKee, William Magner, Thomas P. Magnier, George E. A. Mitchell, Thomas J. S. Moffett, James M. O'Reilly, Alexander Patton, B.A., Samuel P. Rea, William Riddell, John Spence, Hill W. White, Robert Young.

Queen's College, Cork.

We are officially informed that the King has been pleased to approve of the appointment of Bertram Coghill Alan Windle, Esq., M.D., F.R.S., the President of Queen's College, Cork, to the Professorship of Anatomy in the said College, to hold such Professorship concurrently with his office of President, and of the appointment of David Thomas Barry, Esq., M.D., to be Professor of Physiology in the said College.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Early Diagnosis of Pulmonary Tuberculosis.—Hammans and Wolman have analysed the records of 1,745 cases of pulmonary tuberculosis met with at the Phipps Dispensary (*Johns Hopkins Hospital Bulletin*, August, 1907). Out of this number they find that 150 cases may be classed as early, and every one of these presented either slight changes in the percussion note, modified breath sounds, or râles. When all three signs were present, the diagnosis was regarded as complete by physical signs alone, but in 61 cases further aid in diagnosis had to be obtained either by examination of the sputum, by the tuberculin test, or by observing the further course of the disease. Out of the 61 cases, a change in the percussion note was detected in 47 per cent.; breath sounds were modified in 61 per cent.; and râles were heard in 53 per cent. In 24 of the cases tubercle bacilli were found in the sputum, and in 24 other cases that did not show bacilli in the sputum a positive tuberculin reaction was obtained. The symptom for which many patients presented themselves was hæmoptysis occurring after a variable period of coughing, while in 16 per cent. of the cases hæmoptysis was the earliest symptom. As regards the tuberculin test more value is apparently to be placed on a negative than on a positive reaction, except when the positive reaction is borne out by the history, the symptoms presented, and the physical signs. M.

The Opsonic Index for Streptococci in Scarlatina.—Banks has investigated the opsonic index for streptococci in scarlatina with the object of attempting to determine what part streptococci play in the complications of that malady (*Journal of Path. and Bact.*, October, 1907, p. 113). He employed Wright's method of determining the index, and made use of four strains of streptococci, one of which was the strepcoccus pyogenes. The index was taken on different days of the disease, and during the period of convalescence. He formulates his conclusions as follows:—(1) In the early febrile period the index is low: it reaches normal with the decline of symptoms, but falls again during the second and third weeks. It again reaches normal during the fourth and fifth weeks. (2) In fatal cases with severe angina, the power is markedly subnormal. (3) The index is low during the presence of such complications as albuminuria, severe nephritis, and secondary adenitis. (4) A persistently low index during nephritis is an unfavourable sign. Fourteen cases in all were investigated, of which five ran a fairly normal uncomplicated course. M.

Microbic Cyanosis.—Gibson again draws attention to the condition known as microbic cyanosis (*The Quarterly Journal of Medicine*, Vol. I., No. 1, p. 29). Five years ago Stokvis first called attention to the causation of cyanosis by intestinal disturbance, and suggested that some toxin absorbed from the alimentary tract led to the formation of methæmoglobin. Later, other cases were recorded, and in 1906 Gibson reported a case in which there was marked cyanosis accompanying chronic diarrhœa. Examination of the blood in this case showed the presence of methæmoglobin, and some nitrites, and the bacillus coli communis was obtained readily in cultures made from the blood on agar. Nitrites also were found in the saliva, but only in small quantities in the fæces. After treatment of the case for several months with intestinal antiseptics, a marked improvement took place. The cyanosis became much less, the general symptoms ameliorated, and the blood no longer contained organisms. The methæmoglobin also disappeared, but traces of nitrites were still found. The author believes that the condition must be regarded as due to a chronic bacillæmia in which the bacillus coli communis is the pathogenic organism at work. M.

The Parathyroid Glands.—Harnett has examined the parathyroid glands found at 42 consecutive autopsies (*Trans. Path. Soc. London*, Vol. 58, Part II., 1907). His anatomical and histological investigations, so far as they have gone, seem to allow of the following deductions, which are of interest at the present time, when so much importance has been attached to these glands. (1) The activity of the parathyroid increases as age advances. (2) The parathyroid normally forms a secretion indistinguishable microscopically from that formed in the thyroid. In diseases such as myxœdema and goitre this secretion is formed in greater quantity. There is as yet no proof that the parathyroid forms any other secretion besides colloid. (3) There is no histological evidence in favour of the view that the gland has a function of its own essential to life, nor are there any grounds for supposing it to be the organ specially affected in any diseases. M.

Chronic Valvular Disease of the Heart.—Carr (*Practitioner*, September, 1907), in a paper on this subject, discusses the difficulty in diagnosis in cases of adherent pericardium. In chronic mitral valve disease the diagnosis is often greatly facilitated by the symptoms of failure of compensation, but many cases in children progress to a fatal termination without the marked development of the so-called "back-pressure symptoms." In Carr's experience many such cases have also an adherent pericardium, and it is to this more than to the valvular lesion that the symptoms present are due. The ordinary signs of this condition, as enumerated in books, apply mainly, if not exclusively, to adhesions between the pericardium and the chest wall, or mediastino-pericarditis. Carr believes that in children with mitral, but no evidence of aortic disease, and a heart so dilated as to give rise to well-marked precordial bulging, there is very considerable probability that the pericardial sac is obliterated, even though no history of pericarditis can be obtained. The presence of subcutaneous rheumatic nodules, he also believes, almost invariably indicates the existence of active heart mischief. K.

Balsam of Peru in Scabies.—Baker (*R.A.M.C.*, *Journ.*, September, 1907) gives the result of this treatment, which has been carried out in sixty cases at the Military Hospital, Arbour Hill, Dublin. The details of the treatment were given in the *Journal* in January and February of this year by Major Porter. In none of the sixty cases has there been any relapse, nor has there been a case of albuminuria though the urine has been examined at regular intervals after the application of the balsam. Baker considers the preliminary hot bath, efficiently carried out, as an essential, but differs from Major Porter in preferring the pure balsam, while the latter used a mixture of glycerine and balsam in the proportion of one to three. The results in the Arbour Hill Hospital have been very satisfactory, and several patients have been discharged from hospital cured twenty-four hours after admission. The drug is expensive, but the short duration of the treatment more than counterbalances this. K.

Cancer of the Stomach.—Packe (*The Med. Chronicle*, July, 1907) brings forward statistics illustrative of this subject based on the post-mortem records of St. George's Hospital during a period of ten years—1890-1900. During this time there were 227 autopsies performed on cases of cancer of the internal organs, and of these cases sixty, or 26.5 per cent., were cases of cancer of the stomach. Cases of cancer of the œsophagus came next in frequency, and formed 15.9 per cent of the total, while cancer of the colon gave a percentage of 15, and cancer of the rectum 7.9 per cent. From an investigation of these returns Packe draws the following conclusions:—That primary cancer arises more frequently in the stomach than in any other internal organ. That though cancer in general is on the increase, yet the increase of cancer of the stomach is greater proportionately. That males are more frequently the subjects of cancer of the stomach than females, the proportion being 1.85 to 1. The most fatal decade of life for cancer of the stomach is from fifty to sixty years. In this period 32.01 per cent. of the cases occurred. That cancer may follow as a late result of gastric ulcer. That 55 per cent. of the growths occur at the pyloric end of the stomach. That perforation of the stomach occurs most frequently when the growth is on the anterior wall. That cylindrical-celled cancer shows a preference for the pyloric end of the stomach, while the largest number of cases of spheroidal-celled carcinoma were of the form invading the entire stomach. That the histological nature of the growth has no effect on the incidence of metastases or of ulceration. That the œsophagus is the chief seat of primary cancer growth in secondary cancer of the stomach, the pancreas following next in order of frequency. K.

The Starch and Opium Enema.—Ryley (*R.A.M.C. Journ.*, September, 1907) states that on several occasions he has seen severe tympanites follow the administration of this form of enema; in one case the tympanites was so severe that it caused cardiac embarrassment and death. He believes that this condition is the result of two causes. (1) The opium causes a paralysis of the rectum which is consequently unable to expel flatus; (2) the fermentation of the starch causes a rapid evolution of gas, which fills the bowel. Ryley has found by experiment that when starch is incubated at the body temperature, mixed with a little fæces, that large quantities of carbon dioxide gas are formed. K.

The Cerebral Localisation of Aphasia, and its Classification on an Anatomical Basis.—Dana (*New York Med. Record*, August, 1907), by means of an ingenious form of graphic representation, describes the typical symptoms of the four chief types of aphasia:—(1) The frontal or fronto-capsular, characterised by aphemia, with retained ability to read, write and understand; (2) parieto-occipital aphasia, characterised by alexia, with ability to speak, write, and understand, associated with hemianopsia; (3) temporal or temporo-parietal aphasia, characterised by anoesia, some mind deafness, paraphasia, much agraphia and alexia, without hemiplegia, but with some astereognosis, anæsthesia, and ataxia; and (4) fronto-lenticular aphasia, the common mixed aphasia, characterised by aphemia, with much agraphia, alexia, mind deafness, and deafness with hemiplegia. The chart by which each case is represented includes 22 functions tested and recorded as "normal," "slightly impaired," "seriously impaired," or "absent." In conclusion, a short discussion of each of the more important of these functions is given, with the anatomical locations and significance of impairment. D.

Diet in Kidney Affections.—Hanssen (*Nord. Med. Ark.*, Stockholm) tabulates the findings in regard to the metabolism of a number of persons on different diets. They show that the amount of solids eliminated in the urine is as large on a strict milk diet as on a meat diet. The demands on the kidneys are thus as high on a milk diet as when meat is ingested. Fats and carbohydrates, on the contrary, made far less demands on the kidneys, the latter less than the fats. He confirms the reliability of the "variability test" to determine the functional capacity of the kidneys. His conclusions are that a predominant or exclusive diet of carbohydrates with a little fat is indicated in all cases in which the functional capacity of the kidneys is reduced to or below the limits of normal sufficiency. Milk and meat, providing the same amount of calories, cause elimination through the kidneys of about the same amount of molecules, while materially smaller amounts of solid elements are eliminated through the kidneys on a diet of carbohydrates with a little fat. He regards a maximal specific gravity of 1.014, or 1.015 under the "variability test" of the urine as an indication that the limits of sufficiency of the kidneys have been reached, and that meat and milk should be restricted. If the specific gravity does not rise higher than 1.013 or 1.014, or there are signs of retention, then meat and milk should be entirely, or almost entirely, suppressed. In case of uremia, nothing should be allowed but gruels with milk sugar. This takes the place of milk in regard to diuretic action. D.

Physical Therapy of Headache.—Riedel (*Berlin. Klin. Woch.*, 1907) discusses the treatment of headache from the standpoint of physical therapy. In cases of hyperemic headache he advises absolute rest, with cold applications to the head, and hot applications or friction to the lower extremities. Colonic flushings are also said to be of value, as well as active purgation. If the headache is of the paroxysmal variety, cold applications to the head, for a minute at a time, and walking in water at a temperature of from 8° to 10° C. for ten minutes at a time, act almost specifically. Naegel's manual head-stretching is also warmly recommended. For headaches of anæmic origin the head is placed low and the scalp is massaged. Hot compresses applied to the forehead or the nape of the neck, and application of warmed cloths around the neck, are also valuable. Massage is the most efficient treatment in cases of rheumatic headache. The hot air douche and warm applications of various kinds may also be used. The same treatment is indicated in cases of neuralgic headache. The author places much reliance on the intelligent use of massage as a means of relieving such headaches, but emphasises the fact that the physician himself must carry out the treatment, and that it can not be applied by rule of thumb, as it were. D.

New Infection of Persons with Inherited and Acquired Syphilis.—(*Dermat. Zeit. Berlin*, 1907.) Stern's patient was a man of 28, who had a primary syphilitic sore, with numerous pale spirochetes, differing in no respect from an ordinary primary infection with syphilis, and yet the man presented the unmistakable signs of inherited syphilis, or syphilis acquired in early infancy, with tertiary phenomena. This makes the ninth case on record, Stern remarks, in which persons with syphilis in infancy, either inherited or acquired during the first weeks of life, acquired a fresh infection in early adult life. He summarises 80 cases of re-infection in cases of acquired syphilis, and draws the conclusion that the re-infection in many instances is conclusive testimony to the complete cure of the primary infection. He emphasises the necessity for teaching patients this, so that those who have had syphilis in the past may guard against contracting it anew instead of considering themselves immune. His experience also indicates that a strong resistant organism may pass through syphilis with the organs comparatively intact and escape the dreaded consequences. The pessimistic idea that a person once infected is always infected, and immune to future infection, should be combated, he declares, for numerous and obvious reasons. D.

Dublin Sanatorium for Consumptives.

The *Dublin Gazette* of last week contains the confirmation of the Local Government Board Order respecting the Dublin Joint Hospital District, under which the Lord Mayor, Aldermen, and Burgesses of Dublin have constituted a Joint Board for the provision, maintenance, and management of a hospital to be used for a sanatorium for consumptives in the following sanitary districts—County Borough of Dublin, Balrothery Rural District, Celbridge No. 2 District, North Dublin District, South Dublin District, and Dalkey Urban District. The Board will consist of 31 members, and all expenses incurred by the Board are to be defrayed out of a common fund, into which shall be paid sums received from the component authorities in respect of the cost of maintenance of patients and the sums recovered by the Joint Board from or repaid to the Joint Board by or for patients.

Royal College of Physicians in Ireland.

The annual dinner of the College will be held on Saturday, October 19th, instead of on St. Luke's Day, which this year falls on Friday.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

THE MEDICAL DIRECTORY FOR 1908.

To the Editor of The Medical Press and Circular.

Sir,—The amalgamation of various London Medical Societies under the title of the Royal Society of Medicine necessitates a great many alterations in the forthcoming issue of *The Medical Directory*, and we shall feel obliged if all Fellows of the Society, or Members of Sections, will kindly give us at once the necessary information. We may say that we have now decided to abbreviate the entries to the following:—Fell. Roy. Soc. Med., or Mem. —— Sect. Roy. Soc. Med.

Many gentlemen, in making their returns, have overlooked the fact that several of the old societies have ceased to be. Of course, we have to delete such entries for the future.—Your obedient servants,

The Editors.

Dr M. P. K.—Owing to unusual pressure on our space during the past few weeks, there has been a little delay in the insertion of papers. We hope to have space for your communication in our next.

A facetious correspondent has sent us the following:—

SELF-MEDICATION.

One curse of the nation is self-medication,
As now we're beginning to find;
While *symptoms* are treated by doses repeated,
The *cause*, of course, never opined.
Then they find the mistake, for the pain or the ache
Is not quite so easily cured,
And they give up the game, and with sadness exclaim:
No! no! it must all be endured!
For everyone gibes at the man who prescribes;
The chemist will suit just as well.
He will always suggest what he thinks is the best,
But the name of no doctor he'll tell.
Christian Science they try, but they find bye and bye
It's not of the slightest avail;
Unless they're neurotic, it's all "Tommy-rotic,"
And they're certain to find it to fail. A. D.

Mr. J. W. Williams.—The estimated population of London, excluding the outer ring, is 4,758,218; that of Glasgow, 847,584; Dublin, 390,691; Belfast, 370,183; Edinburgh, 345,747. If your inquiry relates to Greater London for comparison, the official number is 7,217,941.

Meetings of the Societies, Lectures, &c

Wednesday, October 9th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. P. J. Freyer: Clinique. (Surgical.) 5.15. p.m.: Lecture:—Dr. G. H. Savage: The Psychoses of the Aged.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Thursday, October 10th.

Royal Society of Medicine (Obstetrical and Gynæcological Section) (30 Hanover Square, W.).—7.45 p.m.: Specimens will be shown by Dr. Eden and others. Short communication:—Dr. A. Routh: A Case of Cæsarean Hysterectomy for Traumatic Atresia of Vagina, the Patient having previously been Successfully Operated upon for Vesico-vaginal Fistula. Paper:—Prof. W. E. Dixon and Dr. F. E. Taylor: On the Physiological Action of the Placenta.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. H. Evans: Cysts and Cystic Conditions of the Neck.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson), X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Throat Operations (Mr. Carson). Lecture:—Dr. Forsyth: Goitre.

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Essentials in the Study of Dermatology.

Friday, October 11th.

Royal Society of Medicine (Clinical Section) (20 Hanover Square, W.).—8.30 p.m.: Inaugural Address: The President (Sir Thomas Barlow). Exhibition of Cases. The patients will be in attendance at 8 p.m.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Dr. St. Clair Thomson: Clinique. (Throat.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Vacancies.

Birmingham, City of, Asylum, Rubery Hill, near Birmingham.—Assistant Medical Officer. Salary, £150 per annum, with apartments, board, etc. Applications to Medical Superintendent.

St. James's Gate Brewery, Dublin.—Resident Assistant Medical Officer. Salary, £150 per annum, with furnished apartments. Applications to the Chief Medical Officer, St. James's Gate.

The Earlswood Asylum, Redhill.—Junior Assistant Medical Officer. Salary, £130 per annum, with board, lodging, and washing. Applications to the Secretary at the Offices of the Asylum, 36, King William Street, London Bridge, E.C.

Manchester, University of.—Senior Demonstrator in Physiology. Salary, £150 per annum. Applications to the Registrar.

Bradford Poor-Law Union.—Resident Assistant Medical Officer. Salary, £100 per annum, with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians, Union Offices, 22 Manor Row, Bradford.

Brompton Hospital Sanatorium.—Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications to the Secretary, Brompton Hospital, London.

Three Counties (Gloucester, Somerset, and Wilts) Sanatorium for Consumptives, Winsley, near Bath.—Resident Medical Officer. Salary, £200 per annum. Applications to the Secretary, at the Sanatorium.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary, £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

Valkenberg Asylum, near Cape Town.—Assistant Medical Officer. Salary, £250 per annum, free board, washing and lodging. Applications to Agent-General for the Cape of Good Hope, 100 Victoria Street, London.

Albany General Hospital, Grahamstown.—House Surgeon. Salary, £200 per annum, with board, furnished quarters, and laundry. Applications to the School Registrar, St. Bartholomew's Hospital, E.C.

Edinburgh District Asylum, Bangour Village.—Second Assistant Physician. Salary, £120 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent, Bangour Village, Uphall.

West Sussex County Asylum and Graylingwell Mental Hospital, Chichester.—Junior Assistant Medical Officer. Salary, £150 per annum, with furnished apartments, board, attendance, etc. Applications to the Medical Superintendent.

Births.

Barlee.—On Oct. 1st, at 6, Coates Crescent, Edinburgh, the wife of Dr. H. J. W. Barlee, of a son.

Mansell.—On Sept. 28th, at Crofton, West Hill, Hastings, the wife of H. R. Mansell, M.R.C.S., of a daughter.

Marriages.

Atkins—Highton.—On Oct. 5, at Christ Church, Brondesbury, Frederick Durnford Atkins, M.B., B.S., M.R.C.S., L.R.C.P., son of Frederick T. Atkins, Chelston Manor, Cockington, Torquay, to Edith Agnes, second daughter of the late Rev. Edward Highton, M.A., Rector of Tarrant-Keynston.

Badgerow—Oxley.—On Oct. 5th, at St. George's Church, Hanover Square, London, George W. Badgerow, M.B., M.R.C.S. (Eng.), only son of A. H. Badgerow, J.P., of Toronto, to Maud, eldest daughter of Herbert Oxley, Esq., of 3, Hans Crescent, London.

Garrett—Hall.—On Oct. 2nd, at the Parish Church, Hampstead, Raymond Reynolds Garrett, M.R.C.S., L.R.C.P., fifth son of Lewis B. Garrett, of Maida Vale, London, to Josephine Bell, daughter of the late Thomas Hall, of Newcastle-on-Tyne.

Ginner—Smith.—On Oct. 1st, at Holy Trinity Church, Southport, Ernest Wightman Ginner, Esq., M.D., of Cannes, France, elder son of the late I. B. Ginner, Esq., of Cannes, to Eiley, younger daughter of the late J. E. Smith, M.D., of Grimsby and Southport.

Motherwell—Parsons.—On Oct. 5th, at St. Peter's, Bayswater, Gavin Black Motherwell, jun., Airdrie, N.B., to Margaret, only daughter of Sidney Parsons, M.R.C.S., and L.S.A., 78, Kensington Park Road, London.

Deaths.

Gallagher.—At Duala, German West Africa, of fever, Dr. John Gallagher, late Bombay Medical Service, aged 60.

Jotham.—On Oct 2nd, Helen, eldest daughter of the late George William Jotham, M.R.C.S., L.S.A., in her 69th year.

Stolterfoth.—On Oct. 4th, at Grey Friars, Chester, Henry Stolterfoth, M.D., J.P., aged 71 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, OCT. 16, 1907. No. 16

NOTES AND COMMENTS.

Socialism and Medicine.

WITH the anti-Socialist campaign that is at present engaging the energies of certain politicians, we have, of course, nothing to do; but we may, perhaps, pause to ask why it is that the Socialists who, we understand, advocate the universal brotherhood of man, seem to take an almost morbid delight in offending every party and class in the country. If the world, socialistically organised, is to be a paradise such as we look forward to in the millennium, it will, we take it, not depend for its success on the prevalence of the spirit of bitterness that animates some present-day Socialists. The medical profession seems to be a particularly red rag to the Socialists, and in their organs we frequently find, either in the editorial or correspondence columns, some attack, veiled or overt, on medical men. Considering that quite a number of medical men are Socialists, and that the profession itself is the only one in the land that shares its acquired possessions freely with those in need, the attitude of the Socialist spokesman is an extraordinary one. Perhaps no more striking confirmation of these assertions could be obtained than by an extract from the Socialist children's catechism which has been sent us. It runs as follows—

"Have poor people objections to the present hospitals?"

"Yes; they are afraid that the doctors and students will make experiments on them."

"Why do doctors make experiments on poor people?"

"Because it gives them experience, which they sell to the rich."

"Do students practice on the rich?"

"No; the rich will not tolerate it."

The Young Idea.

Now, if malignant and spiteful lies of this kind are taught to the rising generation of Socialists, we may expect it to mature in time into a race even less regardful of truth and shame than the people who poison its young mind with atrocious statements such as these. The meanest and most sordid motives are here imputed to the doctors, and they can have but the effect their authors desire—namely, to disgust and sicken every honourable man of the Socialists' propaganda and methods in this country. We cannot but feel, however, that such shameful lies would be disowned by the philosophical Socialists, who believe in Socialism as a creed, and set themselves to practice its doctrines of self-abnegation and sharing with the poor, and who are not Socialists for the sake of self-advertisement or self-interest. At the present day the beauty of Socialistic precepts seem about as much overlaid with undesirable personalities as the beauty of Christianity was in certain mediæval periods.

Notification of Births Act.

THERE are several authorities now debating the advisability of adopting the Notification of Births Act, and one or two which have already done so. We are glad to see that the aspect of the Act which is so offensive to medical men is being represented in most quarters, and last week, at Battersea, Mr. Burns' own constituency, where the adoption of the Act was regarded as a foregone conclusion, the matter has been adjourned for consideration, in consequence of strong medical protest. It is greatly to be hoped that medical men all over the country will make a powerful effort to impress their views on the local authority. It must be made plain that there is no hostility to the principle of the Act, or any desire to obstruct or hinder the health authorities, but quite the reverse. But it should be represented that the Act, as passed, is most offensive to the profession, in that they are bound under penalty to see that their patients perform their civic duties, and that the character of half-spy and half-policeman is not one which practitioners care to undertake. There is no reason why medical men should be dragged into the measure at all, and if this aspect of the Act is presented to local authorities, and they can be persuaded to represent it to the Local Government Board, it would be a very simple matter for a one-clause Bill to be passed through Parliament next session to rectify this injustice.

Melbourne Hospital Staff Election.

A CORRESPONDENT in Melbourne has sent us a description from the *Melbourne Argus* of the proceedings that took place at the election of the honorary medical staff at the Melbourne Hospital in August. It is difficult for anyone living in the antiquated atmosphere of the old country to understand how anything so derogatory to professional dignity could take place in any country at the present day. Apparently the whole medical and surgical staff was chosen, the election being by the subscribers, anyone paying a guinea having a right to vote. According to the *Argus*, the scene resembled "a third-rate race meeting or a Tammany convention." The street was crowded with cabs, carriages and motors, bringing voters to the poll, and the hall where the polling took place and the approaches were crammed with professional canvassers, who are on hire for any election that may be going on. As people arrived they were button-holed, cajoled, and persuaded. Cards were thrust into their hands, and yells of "Don't forget Dr. Dash," or "Give one vote to Dr. Blank," made the place hideous. The candidates were rushing voters to the tables, and a smart man could, it would seem, get a supporter from someone else by dint of a little tact. Nor were the ordinary amenities of a fair election observed, for hundreds of ballot-papers were taken out of the room to be marked, and faggot-votes were created by a special department, in which people came and paid a sovereign—whose sovereign nobody cared—and received a vote on the spot. At any rate, nearly three hundred votes were thus created on the last day.

And Some Reflections. Now how far responsibility for such undignified proceedings rests with the management and constitution of the hospital, and how far with the medical men concerned, of course we are unable to say, and we can only grieve that the fame and honour of medicine should be so besmirched. Considering that honorary hospital posts are supposed, in theory at least, to represent a form of service to people so poor as not to be able to pay for medical attendance, it can only stultify the profession in the eyes of the public if such appointments are sought with all the vulgarity of public suffrage. On the other hand, if it is desired by the hospital to secure the services of the most competent physicians and surgeons, we can only say that the method adopted seemed so designed to cater for the least scrupulous, whatever its results may be in practice.

Vivisection Horror. It is not a little instructive to notice the way the newspapers are dealing with the latest volume of evidence before the Royal Commission on Vivisection. Naturally, the more responsible journals give fairly impartial summaries; but a shorter and more picturesque way adopted by others is to drag out a certain passage or incident which seems to support the views of the particular journal, and to paste it large upon its sheet. Thus the *Morning Leader* flashed out last week with an article headed, "Vivisection Horror. Official Denials of Obvious Facts." Now anti-vivisection, anti-vaccination, and anti-medical generally as the *Morning Leader* is, it is certainly not edited without a sense of humour, and if ever the weakness of the anti-vivisection case was exposed, it is by the fact that this "Horror" was the worst thing that could be dished up. In reality, it was the most hollow farce. The Hon. Stephen Coleridge was written to this summer by an undergraduate at Keble College, Oxford, who said that his rooms were opposite the University Museum, and "nearly every day he was harassed by the piercing yells of a dog in agony." The gentleman in question visited the museum, and ascertained from an "official" that vivisection was carried on there. The letter contained the usual vituperative remarks about scientists, and several gentlemen endorsed the complaint. Mr. Coleridge promptly wrote to Professor Gotch, who replied that no vivisection experiments on dogs had been carried out in the laboratory during the present year.

And Four Puppies. "But," slyly added the Professor, "four puppies were born and kept in the adjoining yard, and the shrill yelps of these animals when at play were presumably the sounds heard by your correspondent." Needless to say, the young gentleman who had made himself so supremely ridiculous was much annoyed at being so neatly and completely bowled out, and he descended to abuse and wild hearsay, calling Professor Gotch a liar and so on. Really the *Morning Leader* must be careful, for what would be left of it but yellowness were it not for its humour, and what can be said for the humour of a journal which calls the delighted yells of four puppies at play a "vivisection horror?"

LEADING ARTICLE.

THE ALLEGED CRISIS IN THE MEDICAL PROFESSION.

First of all, let us ask if a crisis is actually at hand in the medical profession. The answer depends a good deal upon what is meant by the term "crisis." If it asserts that the profession, as a whole, is likely to come to an untimely end in the near future, and to wither away and die for sheer lack of sustenance, then the notion may be at once dismissed. If, on the other hand, it indicates that the medical practitioners of the United Kingdom are to-day faced with scanty and diminishing incomes, with increased living expenses, with a lessened field of work, and with the handicap of competing hospital and quack practice, there is truth enough in these things and they undoubtedly point to a crisis. The phrase, used in the latter sense, simply expresses the plight of a long-suffering profession, whose good nature has been abused, and whose rights have been violated on all sides. The crisis is realised more or less in the higher ranks of the profession, among the consultant and the specialist. Its more serious effects, however, are experienced by the general practitioners, for no profession, however high and noble its ideals, can hope to survive on any but a sound economic basis.

Truth to say, the public are themselves greatly to blame. As a general statement they do not pay their medical attendants for more than two-thirds or three-quarters of the service rendered. Obviously that means a good deal in the case of small incomes, where appearances have to be kept up, and where expenses are heavy. Read in that light, the authoritative estimate of the average income of the British practitioner, at £200 or £250 a year, reveals a crisis in itself. It speaks volumes for the high standard of honour which the public know to expect from medical men that so poor a profession should contain so few black sheep. After all said and done it must be confessed that medical men have themselves to thank for much of the mischief. They have no powerful organisation like the lawyers, to maintain an adequate scale of fees and to punish promptly all illegal practice. The General Medical Council enforces an iron discipline upon the qualified medical man, but, unlike the Incorporated Law Society, takes no heed of the inroads of the unqualified practitioner. In the latter particular the powers both of the Council and of the profession are grievously curtailed by defective medical acts. While these acts carefully control the education and test the knowledge of the medical man, they nevertheless permit any charlatan without the shred of a pretence to medical training to practice any branch of medicine so long as he does not style himself a doctor. The reform of the medical acts, indeed, lies at the root of a great part of the evils. The State, however, so far from seeking to advance the status and prosperity of the deserving class concerned, seldom fails to seize any opportunity of exacting from it further gratuitous service, as, for instance, in the Notificaton of Births Act recently passed through Parliament. In doing this the powers that be have simply kept to the precedent whereby the death certificate, another important document, is also exacted without fee or reward. It may safely be assumed that no Government, however strong, would venture to impose a responsible duty of that kind upon the legal profession without fixing an adequate fee in return.

As medicine becomes more and more an exact science, and as disease after disease is banished from our midst, it follows that the field of medical practice must be correspondingly lessened. What a vast sum of money the medical profession has been (quite legitimately) deprived of during the past ten years by the reduction of small-pox almost to vanishing point! What is true of small-pox will one day be true of many other diseases. Nevertheless, so far as one can see, there will always be need of a certain number of medical men to act surgically and to advise the individual how to preserve his health as well as to keep up public prevention at the highest possible pitch of perfection.

It has been suggested that the whole medical service should be brought under the control of the State. The suggestion seems Utopian, at any rate in our present stage of civilisation. So far the State has left the medical man, after a costly and arduous training, to sink or swim without further attempt at his protection. Is the State likely to alter its ways by adopting the *rôle* of a master? Not many years ago, by a stroke of its legislative pen, whole armies of fever-stricken patients were taken away from the care of private practitioners and lodged in public infectious hospitals. The resulting benefit to the community has been, in part at any rate, at the cost of the medical profession. Has the State ever shown any wish to make good that loss to the medical profession, even by way of defending their elementary right against unqualified persons?

It is clearly a matter of supreme importance to the community to maintain a service of competent and flourishing medical practitioners. As things go they are threatened with the atrophy of an indispensable professional class. The crisis is a real one and the remedy to a great extent in the hands of the community.

"THE GRIP OF THE SPECIALIST."

Under the sensational title of "The Grip of the Specialist," one of the young lions of the *Nation*, which is our old friend the *Speaker* rejuvenated, has been roaring at the growing tyranny of the medical profession, and reverberations of the roar have found their way into the leading columns of the *Tribune*. Both these excellent papers profess to shiver at the power which is passing into the hands of medical men, and we fear, although they are careful not to commit themselves too definitely, at the way in which it is used. "Everywhere among the educated public we encounter signs of disquietude, distrust, sometimes of vocable revolt, against the dominion of the doctor, and the elaborate professional and business apparatus that has grown up around him." Thus runs the "vocable revolt" of the *Nation*, and that of the *Tribune* is like unto it. Well, it is always an excellent thing to have a little outside advice, and we must not be offended so long as it is for our souls' good, but we confess that this "vocable revolt" on the part of the public has till now not reached our ears, though there has been some vocability and even revolt on the part of the medical profession at the way they have been treated by the public, and in our opinion there should be a great deal more. The *Nation* tells us that most sane laymen "tremble at the power of the new priesthood," and that now that the Church has lost influence its mystical authority has devolved upon the medical profession. "The mantle of Elijah has fallen on Elisha." Now, without disrespect to the Church we may perhaps be so bold as to say that it seems to us an excellent thing that the medical part of its work has been handed over to a *cadre* organised and trained *ad hoc*, and that the Church has been left free to pursue its spiritual functions, in which it has always been considerably more successful than it has in dabbling in medicine. But knowledge is power, and whereas the medical man has no more authority than any other citizen maliciously to wound or officially to overawe His Majesty's lieges, yet he is granted a power to inflict wounds on and prescribe dangerous drugs for those people who voluntarily place themselves in his hands. A medical qualification is absolutely valueless except as a passport to practice, and practice is, or should be, entirely a matter of personal confidence between doctor and patient. In other words, a doctor has no power except over those people who voluntarily place themselves in his power, and they can remove themselves from his care whenever they like. Where the "grip of the doctor" comes in, we fail to see; anyone who continues in the "grip" of a doctor he does not believe in is a fool. The specialist is a particularly dreadful fellow, according to the *Nation*. "The absolute confidence with which a specialist of repute will impose a long, painful, and expensive treatment, which other specialists of no less repute condemn, bewilders and amazes those new to the annals of modern medicine." But his amazement apparently does not prevent the layman going to the specialist, even though "when he (the layman) is taken ill it becomes a matter of chance whether he is forced to undergo a dangerous operation, is put on novel and hazardous diet, is sentenced to two months' close confinement, or to a long term of distant exile," and yet he dares not refuse the treatment or take further advice! Really the specialist's grip seems to us remarkably weak, and assuming for the sake of the argument his saturnine character, he seems only likely to maintain his grasp on those foolish people who are too weak to enter into "vocable revolt." Indeed, we should not feel ourselves such villains after all that the *Nation* says, if it said but that, but we consider it utterly unworthy of a journal with traditions of the *Speaker* behind it to descend to general innuendo with regard to medical men receiving secret commissions from hotel-keepers, chemists, and members of similar callings. We should think it beneath our own dignity, if merely out of spite, and without a tittle of evidence, we suggested that the editor of the *Nation* was bribed by politicians to support their views; but he on his part does not hesitate to throw out an equally unworthy charge against the medical profession. To bolster up a weak case with a vindictive charge is not the type of journalism we expected from the *Nation*, to whose success in the enterprise before it we have looked forward with pleasure.

CURRENT TOPICS.

Anæsthetic Fatalities in London Hospitals.

THE question of death under anæsthetics is one in which both the medical profession and the public are deeply interested. In spite of many individual and collective investigations there is still much to be learnt regarding the scientific side of these unhappy accidents. As we have already pointed out in the columns of the MEDICAL PRESS AND CIRCULAR, it would be an important logical step in the formal analysis of the situation were one to secure accurate comparative statistics in full detail from the various London hospitals. In order to avoid any invidious criticism the returns would be made under letter or number, without the publication of any names. It seems perfectly obvious that figures thus presented would indicate useful lines of further investigation. Another rich field of data lies in the Coroner's Court. We are glad to see that Dr. Waldo, the Coroner for the City of London, is making an exhaustive inquiry into the anæsthetic deaths that take place within his districts, which include the great hospitals of Guy's and St. Bartholomew's. In another column we publish a short summary of such an inquest held by him on the body of a woman who died on the 3rd of October at Guy's Hospital, while undergoing an operation for exophthalmic goitre. Chloroform was administered by the house surgeon, who stated he had given anæsthetics in some 98 cases, and who admitted he knew the special anæsthetic risks of that particular operation. He assumed full responsibility, but later the surgeon said he himself was partly responsible for the administration. The Coroner naturally inquired why in a non-urgent case of admitted difficulty the services of one of the eight staff anæsthetists attached to the Hospital were not called into requisition. The authorities of Guy's may have some satisfactory explanation to offer, but meanwhile the public will probably be inclined to agree with the jury that the present system is to blame. The matter is in various ways one that requires careful handling. We all know that medical men must acquire a knowledge of anæsthetics, but there is no apparent reason why in a large hospital juniors should not be kept under constant supervision. What is the use of staff anæsthetists if they are not required to attend cases of special difficulty, either at administration or at supervision of administration?

Unvaccinated Teachers

THE educational sea appears to be doomed to manifold storms. In the London County Council a fresh disturbance has arisen over a recent resolution framed in the interests of preventive medicine. It was resolved that in the event of smallpox arising in a school or college any unvaccinated teacher refusing to be vaccinated within twenty-four hours will not only be excluded, but will not be paid any salary during the period of absence. It seems clear that on moral grounds the teacher, however much he may be entitled personally to reject vaccination, must yield to the views of the majority when the welfare of others is concerned. While it may be conceded that a school authority is acting on the lines of commonsense prudence in excluding an unvaccinated teacher from school during a smallpox outbreak, we fail to see why such an unprotected person was ever allowed to assume a position of the kind. Indeed, it almost seems that to allow unvaccinated teachers to mingle with State school children is to permit an open violation of laws that have been formally adopted by the legislature, with enormous resulting benefit to the community. The unvaccinated school teacher is typical of the restless band of anti-vaccinationists ever on the look out for some loophole of evasion to a most salutary law.

Butchers and Tuberculous Meat.

THE war against consumption can hardly be waged seriously until steps are taken to exclude tuberculous meat and milk from the national commissariat. Chester, at any rate, is taking the matter vigorously in hand, so far as cattle are concerned. The Corporation of that ancient city have been forced in self-defence to bring pressure on the farmers attending Chester fairs, and to demand from the latter a guarantee against tuberculosis in their cattle. The butchers suggest that the farmer shall insure approved beasts, and that where a butcher has a guaranteed carcase seized he shall be recouped to the extent of two-thirds of the price. This proposal has naturally caused a good deal of commotion amongst the farmers, who belong, as a rule, to a somewhat conservative class. They have held, so it is reported, a crowded meeting, at which strong opinions were expressed that compensation should be paid for condemned carcases out of public money. Few political economists would question the principle involved in granting State compensation for the compulsory destruction of tuberculous cattle. On no other basis would a law to that effect be enforced in the United Kingdom. For a sum costing far less, say, than the late Boer war the country could be freed several times over from tuberculous cattle. Some day this inevitable reform will be forced upon the community.

Research Scholarships on Effects of Alcohol.

FOR several generations a kind of scientific or semi-scientific warfare has been waged over the question of alcohol and its effects upon the human body. *Mirabile dictu* the mass of observations, chemical, biological, clinical, and pathological have not yet been reduced to established and scientific generalisations. Truth to say, the medical mind is chaotic as regards the desirability of retaining alcohol as a beverage. On the other hand, most practitioners will endorse the view that alcohol has a distinct value as a therapeutic agent in sickness, and perhaps also as a stimulant in various depressed physiological states. The recent issue of a manifesto and a counter-manifesto signed by some of the most distinguished names in the medical world, however, marks the sharp divergence of the twentieth century on so important an everyday matter as the consumption of alcohol by the community. The National Temperance League has taken the practical step of founding research scholarships for the purpose of investigating the effects of alcohol. It is to be hoped, however, that the task will be entrusted to absoluely impartial scientific investigators, for there is hardly any sociological matter in which the individual judgment is apt to be more biassed by personal views than that of the proper place of alcohol in the world's economy.

College Athletics.

It is a matter of some regret that in most American colleges and universities athletics are overdone. One of the consequences is that there is a strong public feeling hostile to the practice of athletics, and all such exercises, good and bad, are likely to come into disrepute. We are assuming that some athletics are good, and in this country, for the present at any rate, there are not many to question the assumption. The severe discipline undergone by all who really engage in arduous sport must have moral and physical effects of some value. As a matter of fact, the lives of distinguished athletes are, in an insurance sense, "good," and old "Blues" are not only long-lived but healthy. On the other hand, there is considerable risk in the overtraining that seems to be prevalent among athletes in America. It is said that in that country it is impossible, or nearly so, for a student who wishes to gain scholastic distinctions to devote any time to games. This is certainly very different from the state of affairs in our own Universities, and is very far from what ought to exist. It is certainly true also that the abnormal development of muscle to which injudicious training gives rise is by no means an advantage to the human economy, and it is probable that deleterious effects on the blood-vessels also result. Under the circumstances, it is not matter for wonder that some of the professional journals in America have declared a crusade against athletics at schools and colleges, and some of them suggest that athletic games should be put on the same level as gambling, and strictly forbidden.

The Tuberculosis Exhibition in Dublin.

The Executive Committee of the Tuberculosis Exhibition, which was opened in Dublin last Saturday by His Excellency the Lord-Lieutenant of Ireland, are to be congratulated on their initiative in starting the first exhibition of the kind in the United Kingdom. In no part of the kingdom, indeed, is such a lesson so much needed, for in none is the damage wrought by tuberculosis so great, and in none are the public health authorities so lax in their attention to their first duty. The committee is further to be congratulated on having brought together a series of exhibits which cannot fail to give instruction of value, and on the great public interest which their enterprise has aroused. It is seldom, indeed, that one sees such a large and intelligent audience assembled to discuss any matter affecting public health as that which listened to Professor Osler's lecture in the Royal Dublin Society's premises on Friday evening. The practical advice given to him as to the means to be adopted by the public in fighting against tuberculosis cannot fail to bear fruit. The exhibition itself is, as may be seen from out description of it elsewhere, admirably adapted to interest and instruct the public in matters relating to the prevalence of the disease, and to the methods to be adopted to prevent its spread. Statistical, pathological, therapeutic and sanitary exhibits help to show the members of the public bodies and others charged with responsibility for the public health both the magnitude of the evil and how it may be met with success. Popular lectures and demonstrations serve to explain those matters which are not obvious in themselves. It is intended that, when the exhibition has spent a few weeks in Dublin, it should be taken on tour to the various large towns of the country, and that every means be taken to bring its lessons home to the public.

PERSONAL.

Mr. T. J. P. Hartigan will give a course of lectures on Dermatology at the Hospital for Diseases of the Skin, Blackfriars, on Mondays, Wednesdays, and Saturdays at 5 p.m., from October 9th to December 21st.

Dr. Hector W. G. Mackenzie will open a discussion at the Medical Section of the Royal Society of Medicine on Tuesday, October 22nd, at 5.30 p.m. The subject will be, "The Complications in Sequelæ of Pneumonia, and the Possibilities of Treatment by Serum or Vaccine."

Dr. MacLennan, of Thurso, was the recipient of a handsome present on the occasion of his leaving Thurso, where he has been in practice eight years.

Professor Francis Gotch distributed the prizes at the opening of the Faculty of Medicine at University College, Bristol.

Mr. Justice Walton will give the inaugural address of the Medico-Legal Society's first meeting at 22, Albemarle Street, W., on October 29th, at 8.15. Dr. W. H. Willcox will give a demonstration on Wounds Produced by Firearms at the same meeting.

Professor Simeon Snell will give the first post-graduate lecture at the Royal Eye Hospital, Southwark, to-night (Wednesday), at 7 p.m. His subject will be "Injuries and Wounds of the Eye, Eyelids, and Orbit."

Dr. Alexander Macphail, Professor of Anatomy at St. Mungo's College, Glasgow, was given a complimentary dinner and a handsome presentation by a hundred medical men of that town on the occasion of his relinquishing his appointment for that of Lecturer in Anatomy at Charing Cross Hospital, London.

Dr. Laurence Humphry has been appointed Assessor for the year to the Regius Professor of Physic at Cambridge.

Dr. E. R. S. Lipscomb has been presented with a valuable clock on resigning his appointment, held for twenty years, of Medical Officer to the Starcross Branch of the Rational Association Friendly Society.

Dr. H. F. Devis has been made the recipient of a presentation by the employees of the Great Western Railway at Bristol on resigning the post of Honorary Lecturer on First Aid, after fourteen years' work.

Colonel F. J. Lambkin, R.A.M.C., of the Royal Army Medical College Staff, has been deputed by the Secretary of State for the Colonies to carry out special investigations in the Uganda Protectorate.

Mr. Girling Ball, F.R.C.S., has been elected to the Luther Holden Research Scholarship in Surgery for the year 1907-8.

Dr. Orr, of Tayport, has been elected President of the Fifeshire Medical Association for the coming year, in succession to Dr. Balfour Graham, of Leven.

The inaugural address of the session at the Meath Hospital and County Dublin Infirmary was delivered on October 9th by Dr. James Craig, M.D., Physician to the Hospital.

Dr. David Rice, Senior Assistant Medical Officer of the Staffordshire County Asylum, has been appointed Medical Superintendent of Norwich City.

A Clinical Lecture
ON
ENLARGEMENTS OF THE LIVER. (*a*)

By W. HALE WHITE,

Senior Physician to and Lecturer on Medicine at Guy's Hospital.

Gentlemen,—It came into my mind, when asked to deliver this lecture, that we are in our daily life constantly examining the liver, and therefore it might not be amiss if this afternoon we discussed some points connected with its enlargements, especially the difficulties of appreciating and interpreting variations in its size.

Sometimes we are, I think, inclined to forget that in infants and children the liver is relatively larger than in adults, for while in an adult it is about 1-36th of the body weight, at birth it is only between 1-18th and 1-24th. More than once I have known forgetfuness of this lead to mistakes.

Feeling the liver is of much greater clinical use than percussing the area of hepatic dulness, and as a rule it is easiest to feel the edge of the liver just outside the edge of the right rectus. It is true that in the epigastric angle a small portion of the anterior surface of the left lobe comes in contact with the anterior abdominal wall, but often in actual practice this cannot be felt, for nowhere in the abdomen is it more difficult to feel through the wall than in that part formed by the upper quarter of the two recti, for they are thick muscles, and cannot easily be pushed in from their attachments. On the other hand, this may be the only portion of the liver which can be felt, especially if the ribs are thrown forwards and outwards, as in emphysema.

With regard to organs resting against the liver, the fact that its superior surface has on it a slight depression made by the heart is of little clinical importance, for the diaphragm here is so firm and dense that enlargements of the heart hardly ever directly affect the liver; but the close contact of the left lobe of the liver to the lesser curvature of the stomach, and the contact of the pylorus with the quadrate lobe are of great importance, for not only may ulcers and malignant disease of the stomach grow directly into the liver, but tumours of the stomach may sometimes be dragged up and down during respiration, moving with the liver. For the same reason tumours of the hepatic flexure of the colon or of the kidney may move up and down with respiration, as both these organs are adherent to the under surface of the liver.

Many mistakes have been made from forgetfulness of the fact that a tongue-like projection of the right lobe may protrude from its lower right-hand part. This projection, which is called Riedel's lobe, is often associated with disease of the gall bladder, such as gall-stones, or with tight-lacing, and is commoner in women than men; but it may be found in quite young children; so in some cases, at least, it is a congenital abnormality. The connection between a Riedel's lobe and the liver may be only peritoneal, in which case the lobe may easily be confounded with a floating kidney, especially as there may be a band of resonance between it and the liver. A Riedel's lobe may also be confused with almost any abdominal tumour which occurs on the right side of the abdomen. It rarely gives rise to any symptoms, but is often associated with those of gall-stones—why, we do not know. However, a Riedel's lobe is not at all common, but still the lower and outer part of the right lobe of the liver may be very difficult to tell from a right kidney. I feel sure that this difficulty is much more frequent than text-books would lead us to expect.

Many conditions unconnected with the liver cause an apparent alteration of it, and these conditions have often been the cause of mistakes in diagnosis. When the body is wasted and the tissues are lax, the organ may drop down. I will allude to the condition of wandering liver presently, but, quite apart from this, a general weakness of tissues may lead to dropping of the liver. I have had a strange experience this summer, for on two occasions I have known men thought to have cancer of their liver because it seemed enlarged, and they were very wasted, but the wasting was really due to diabetes, and the liver, although a little enlarged, appeared to be much larger than it really was, for it had dropped considerably. Again, when the liver is enlarged and heavy, it is very liable to fall, and it is no uncommon thing to find that the nutmeg liver of the patient with heart disease, who sits propped up in bed, has dropped two inches, for it may be ascertained, even when there is no emphysema, that the upper limit of the hepatic dulness is lower than it should be, and then, of course, the liver is not as large as mere palpation appears to indicate. Again, alterations in the chest lead to depression of the liver, which may be erroneously thought to be enlarged. Thus, in an extreme case of fibrosis of the lungs, with adherent pleura, I have seen the sucking-in of the ribs on inspiration lead to depression of the liver down to the umbilicus. Again, deformities of the chest due to rickets or curvature of the spine may lead to great depression of the liver. With a very large collection of fluid in the right pleural cavity, the liver may be depressed, but I would suggest that there is much misconception on this point, and that depression of the liver by a collection of pleural fluid is much rarer than is commonly believed. The reason is that, owing to its firm attachments, it is not easy to depress the diaphragm, and the fluid more readily makes room for itself by compressing the lung and pushing over the heart. When, however, there is a large amount of pus in the right pleura, the liver will be more readily depressed than by simple fluid, for in the case of an empyæma the diaphragm itself becomes inflamed and so weakened, and, even with pleurisy, if it affects the diaphragm, the liver may appear to be a little depressed, for if the pleural surface of the diaphragm be inflamed, the pain of moving the muscle prevents the patient doing so; hence the diaphragm is kept in a constant position of inspiration, and the liver being also constantly in the position of inspiration, appears depressed. This may be the explanation of the statement that the liver is depressed in pneumonia of the right lung.

Talking of pleural leads our minds to pericardial effusion. We are usually told that extreme pericardial effusion will depress the liver, but I think this must be very rare. It certainly is in my experience, and I should expect it to be so, for the pressure would have to act through the very firm central part of the diaphragm. A subdiaphragmatic abscess being below the diaphragm will, however, depress the liver considerably.

We may get into difficulties when the liver has been altered by tight lacing. Often quite a slight degree will, as is well known, lead to the formation of furrows on the liver evidently corresponding to the ribs, but furrows which obviously cannot correspond to the ribs are sometimes thought to do so. They are too vertical for furrows due to ribs, and it has been suggested that they are due to the fact that the liver is compressed laterally during inspiration, and expands again during expiration. Tight lacing may, by local constriction, lead to the formation of such a deep furrow that part of the liver during life is apparently separated from the rest. Recently a man was in the hospital with what was thought by many who saw him to be an elongated tumour lying transversely in the

---

(*a*) Being the Opening Address delivered before the North-East London Clinical Society on October 3rd, 1907, at the first meeting of the Session, 1907-1908.

abdomen, but it was nothing but the lower part of the liver nearly cut off from the rest by the pressure of a belt he had worn. The furrow may be so deep that the blood supply of the isolated portion of the liver is impaired; then I have seen fatty change confined to such a part.

The effects of corsets upon the liver as a whole will depend upon the position of the pressure. Most commonly the liver is forced down, flattened and elongated from above downwards. The liver thus forms an apron covering much more of the abdominal viscera than is natural, but some of the intestines may get in front of it. The pressure often leads to a transverse depression across the right hand lower part of the right lobe, so that a more or less detached piece of the liver lies over the right kidney, and is, indeed, an artificial Riedel's lobe, and may lead to the same difficulties of diagnosis. When the pressure is by lacing applied lower down, the liver is pushed up into the chest, and is thickened in its vertical diameter.

Various abdominal conditions alter the position of the liver, and the ease with which its size may be ascertained. Contrary to what might be expected from some teaching, it is, I think, quite rare for any enlargement of the liver to lead to upward extension of the hepatic dulness. This is what we should expect, for the mere weight of the enlarged liver will lead to its falling, and as the resistance of the intestines and abdominal walls is much less than that of the diaphragm, it will grow in the direction of least resistance. Enlargement of the hepatic dulness upwards is best seen when some local disease of the liver directly implicates the diaphragm. Thus an abscess of the liver will grow from the upper surface of the liver, soften the diaphragm, and extend upwards; a hydatid will do the same. From this it follows that when there is an extension upwards of hepatic dulness, it is a local extension, forming a dome-shaped addition to the hepatic dulness. Very large collections of ascitic fluid, or very large abdominal tumours, may push the liver up, and so lead to an increase of hepatic dulness upwards; but this is not common, for such tumours or collections of fluid will more readily cause protrusion of the anterior abdominal walls and compression of the intestines.

When working at the bedside, it is most important to remember that there are three moderately common tumours which lie transversely in the abdomen, and so may be thought to be the lower margin of an enlarged liver. They are a stomach affected with malignant disease, especially when the growth infiltrates much of the greater curvature; malignant disease of or impaction of fæces in the transverse colon; and the great omentum thickened and puckered up towards the transverse colon by some form of chronic peritonitis. Any of these tumours may move up and down with respiration, for they are all directly or indirectly attached to the liver, but their movement is not usually so extensive as that of the liver should be. And a band of resonance may sometimes be detected between the liver and the tumour, or the edge of the liver may be felt above it. Enlargements of the pylorus and thickening in connection with a gastric or duodenal ulcer may be difficult to tell from an enlarged gall-bladder, not only from their position, but because they may move up and down with respiration.

The hepatic dulness may be altered by gas. Thus it may be almost obliterated by the descent of an emphysematous lung, and a slight lowering of the upper margin of the hepatic dulness from this cause is quite common. Another result of emphysema is that the lower ribs stand out so far, in a position of extreme inspiration, that they bring the upper part of the abdominal wall so far forward that it is often quite impossible to feel the liver. This state of affairs is by no means uncommon.

When, as in perforative peritonitis, free gas collects in the abdominal cavity, it usually gets in front of the liver, and so may diminish the hepatic dulness; but this sign is, in my experience, more often absent than present in perforative peritonitis. On the other hand, obliteration of the lower part of the hepatic dulness by no means always indicates that there is free gas in the peritoneal cavity, for coils of intestine, or the colon, may get between the liver and the anterior abdominal wall. This is of no clinical significance.

As we have been talking about conditions which push the liver out of place, we are naturally led to a consideration of a wandering or movable liver. To this state of affairs the term hepatoptosis is often applied, and by it we mean a liver which, being unduly displaceable, leaves its normal position and forms an abdominal tumour. It is particularly to be noticed that a liver displaced by a tumour or any other cause is not a wandering liver, for it is just as fixed, only in an abnormal position, as a normal liver; but a wandering liver can be easily moved about. Further, as clearness of thought is dependent upon clearness of expression, we ought, I would suggest, never to use the unfortunate phrase "partial hepatoptosis." It has been applied to a Riedel's lobe or to pieces of liver more or less cut off from the rest of the organ by wearing a band or belt. It should be discarded, for it has nothing to do with hepatoptosis proper; but it is worth remembering that sometimes the part of the liver cut off from the rest by wearing a band has been thought to be the whole liver, and has been considered to be an example of hepatoptosis. Another phrase that should be avoided is floating liver. The liver, suspended by its various ligaments, always floats in the abdomen, and therefore the phrase, floating liver, does not designate an abnormality. Yet another bad term is that of total hepatoptosis. Strictly speaking, that would mean that the liver could be moved about in the abdomen to an indefinite extent, which is absurd. So much attention has of late years been directed to Glénard's disease that there is an impression, I think, that a wandering liver is commoner than it really is. It is, I would suggest, very rare. In a well-marked case, owing to absence of support, the organ drops and rotates on a transverse axis, so that the upper diaphragmatic surface comes in contact with the abdominal wall, and the anterior surface points a little downwards. The result of this is that a large amount of liver comes in contact with the anterior abdominal wall. Such a liver may be felt to be a large flattened tumour extending down to or below the umbilicus. It forms a visible protrusion, moves up and down with respiration, can usually be pushed back into its normal position when the patient lies down; indeed, sometimes on lying down it goes back of its own accord, only to fall again when the patient stands up. It is movable laterally, and can with the hands be rotated round a vertical axis. If it has dropped far there is hardly any hepatic dulness in the chest, and the hand may even be passed up between the ribs and the liver. In such a case there is a depression at the upper part of the abdomen, and this is very characteristic. We need not spend more time on hepatoptosis, as it is so rare.

We now pass on to consider enlargements of the liver proper, for hitherto we have only considered conditions which appear to make the liver large, but do not really do so.

When we pass our hand over the abdomen and feel an enlarged liver, the first thing that naturally arrests our attention is whether the enlargement is uniform. Now the diseases which enlarge the liver, but not uniformly, are hydatid, abscess, growth and syphilis. The enlargement of both hydatid and abscess—if the abscess is of the usual variety—is local in one part of the liver, the rest being healthy; but with growth and syphilis the enlargement is usually of the greater part of the liver, although it is very often irregular. Hydatid and abscess are in this country rare, but, unfortunately, malignant disease is not, for searching our hospital records shows that, of all persons in whom at death malignant disease is found, about 50 per cent. have secondary deposits in their liver, and no organ is more often the seat of secondary deposits. Therefore it will not be amiss if we first consider some points about the enlargement due to cancer of the liver. In the first place, cancer causes the liver to be heavier than any other disease of it. I have known the liver weigh 19 lbs., and even heavier weights have been recorded. It is quite true, as the books tell us, that the nodule of growth may be umbilicated, but it is very rare for this umbilication to be tangible through the abdominal wall, but when it is, the fact is, I would suggest absolutely diagnostic of cancer. So, too, is a very sudden increase in size of a lump in the liver. I have known one to considerably increase in size in a single night. This must, I think, always mean that the swelling is malignant, for the sudden increase must indicate hæmorrhage into the tumour, and the only tumours of the liver into which hæmorrhage can occur are those of a malignant nature. If the growth is breaking down, it may feel soft, and give an obscure sense of fluctuation; but this is rare, and is more in favour of abscess or gumma than growth. If the liver has considerably increased in size in a week, it is strongly suggestive of growth, for the liver never enlarges so quickly as when affected by a rapidly growing growth. The age of the patient is of importance, for cancer of the liver is almost unknown at an earlier age than 20. Before, in a doubtful case, passing an opinion that a liver is not cancerous, the patient should be made to take a deep breath, for it is just possible that a tumour under the ribs may thus be felt. Of course, if most of the cancerous masses are at the upper part of the liver, it may be impossible to feel them during life, but failure to do this is rarely due to the fact that the cancerous masses are in the centre of the liver, for in the post-mortem room we hardly ever find cancerous nodules in the interior of the liver if none are to be seen on the exterior. But we must by no means go away with the impression that lumps can always be felt during life if the patient has malignant disease of his liver. As pointed out, they may be in the upper part or they may be on the under surface, or they may be too small to be felt, or the abdominal wall may be too rigid, or, again, there are certain rare cases in which the new growth infiltrates the whole liver, which is then enlarged and hard, but no nodules can be felt. We should never omit to feel the umbilicus, for the growth may spread along the round ligament to it, and, of course, we ought always to examine for enlarged glands over the left clavicle. When we bear in mind that malignant disease of the liver is nearly always secondary to malignant disease elsewhere, it is not surprising to learn that in half the cases in which in the post-mortem room malignant disease of the liver is found, it was unsuspected during life, for the primary malignant disease often kills before the secondary deposits in the liver have become of any great size.

Perhaps this is a suitable opportunity to refer to some difficulties of diagnosis with which I have been struck. We are often presented with this problem: Here is a patient with a large hard liver, and he is jaundiced. Has he malignant disease of it?—for in many cases the nodules of growth cannot be made out by palpation. About half the patients in whom during life malignant disease of the liver is suspected have jaundice and it is of great importance to bear in mind that the most frequent cause of long-standing jaundice is malignant disease. Jaundice in this condition may vary in depth a little from day to day in its earlier stage, but when once it has appeared it will continue, for it is nearly always due to the pressure on the bile duct of a gland in the transverse fissure, which has become enlarged from the deposition in it of malignant growth. The skin, slowly and deeply stained by bile, gradually becomes more and more green, and ultimately assumes a peculiar earthy, dark green tint, which, especially if the patient be aged and wasted, is almost diagnostic of cancer of the liver. There are few things more characteristic in medicine than to see an aged, grey-haired patient, extremely wasted, with dry, dark green skin hanging in loose folds, lying perfectly still, so drowsy that he is more dead than alive. If we turn down the bed-clothes, the liver may be seen deforming the shape of the abdomen, and it will be noticed that the sheets are stained yellow either from urine or sweat. It is excessively rare to get this green jaundice in any other condition than malignant disease.

Mistakes have occurred from not remembering that the evening temperature is often raised to some point between 99° and 101°, or even more; this may continue regularly for weeks, and there may be a leucocytosis up to 15,000. Only this summer I saw a patient in whom the characteristic feel of the liver made most of those who saw him pretty confident he had malignant disease of it. But some, arguing from the wide daily fluctuations of temperature, and the fact that there was a leucocytosis up to 15,000, thought there must be an abscess. The liver was explored, and was found to be affected with growth. In such a case of difficulty, the absence of rigors would be a point against pus, and the leucocytosis in abscess of the liver is usually considerable.

It may be hard to tell between a cirrhotic liver and one affected with malignant disease if nodules of growth cannot be felt but the liver appears uniformly enlarged. If the tangible lumps are large, there is no difficulty, for, as Sir William Jenner used to teach, if any of them are bigger than a cherry, the case cannot be one of cirrhosis, and the increase in the size of the liver is never so rapid as it may be in growth. It is only in the case of cirrhosis in which the liver is enlarged that difficulty is likely to arise, and in those cases the jaundice is rarely deep, and, I think, never green. Ascites is in favour of cirrhosis.

Impaction of a stone in the common duct may give rise to difficulty, but when there is a doubt the case nearly always turns out to be one of growth, for it is much the commoner, and it is rare for the impaction of a stone to last long enough for the jaundice to become very chronic. Usually the stone lying in the part of the duct which lies in the duodenum ulcerates its way into the duodenum, and the jaundice passes away.

Formerly primary malignant disease of the liver was thought to be much commoner than it really is. Frerichs gave the proportion of primary to secondary growths as 1 to 5. Now I think it is thought to be rarer than it really is. At Guy's Hospital the proportion of undoubted primary to secondary hepatic carcinoma is about 1 to 25, and other hospitals show the same. The reason for this discrepancy is that the older writers regarded cases of primary malignant disease of the gall bladder as examples of primary malignant disease of the liver. There are some interesting facts about primary malignant disease of the liver: it is commoner in men than women, although the secondary form is commoner in women than men. Probably it will be found that the temperature is more often raised in the primary than the secondary form, and jaundice is, if present, usually slight, and comes on late, and rarely, if ever, becomes dark green. The reason for these differences is almost certainly that the primary disease is, as a rule, more rapidly fatal than the secondary—indeed, it is extremely rare for the primary disease to last more than four months after the symptoms have first declared themselves. Mention of primary disease of the gall-bladder leads me to suggest that it is much more frequent than is usually supposed. Dr. N. F. Ticehurst found that among 11,031 post-mortem examinations at Guy's Hospital, there were 45 examples of primary carcinoma of the gall-bladder, and in 43 of these, or 95 per cent., gall-stones were present; in the same 11,031 post-mortem examinations there were 15 cases of primary carcinoma of the bile ducts, and in 75 per cent. of these gall-stones were present. These figures strongly suggest that gall-stones are the cause of the cancer, a view which is supported by the fact that the incidence of age and sex in the cases of gall-stones and carcinoma of the biliary passages is the same in both. Sometimes a definite history of gall-stone colic precedes the symptoms of carcinoma of the biliary passages, and sometimes an examination of the specimen strongly suggests that the gall-stones preceded the cancer. I need not trouble you here with the figures, but an analysis of our cases at Guy's makes me strongly suspect that in 20 per cent. of patients who have gall-stones, carcinoma of the biliary passages will follow, and this suggests that gall-stones should be much more often removed by the surgeon than is commonly done. Inasmuch as patients who are jaundiced bear operation badly, it would appear that the right thing to do is to remove them at a time when they are not causing biliary obstruction.

Sarcoma of the liver as a primary growth is excessively rare, and secondary sarcoma cannot be diagnosed from cancer unless we know that the primary seat of the disease is sarcomatous.

Syphilis is a very interesting cause of an enlarged liver. Taking first acquired syphilis, it is only in the tertiary stage that the organ is enlarged; it may be lardaceous, but that produces a uniform increase, and we are only here discussing irregular enlargements. These occur because syphilis produces a great increase of fibrous tissue and gummata. In 20 years at Guy's Hospital I find these effects of syphilis on the liver in the post-mortem room occurred 95 times, and in 23 out of the 95 cases gummata were present, and in the remaining 72 there was only scarring of the liver by fibrous tissue. Sometimes scarring and gummata were present in the same liver. During these 20 years about 9,500 post-mortem examinations were made, which shows that 1 per cent. of those who die in a general hospital have syphilitic fibrous or gummatous changes in their liver. As the fibrous tissue is so striking, the phrase, syphilitic cirrhosis, is often used, but this is a pity, because a syphilitic liver never resembles one affected with ordinary cirrhosis, for the new fibrous tissue forms great bands, several of which usually start from a common point and cut the liver up into large areas, which consist of perfectly healthy liver. In alcoholic cirrhosis the areas are never bigger than a hobnail, and the hepatic cells in the hobnail are fatty. These great fibrous bands, by their contraction, form scar-like depressions on the surface, and these may be so numerous and deep as to cut the liver up into a number of irregular masses, leading to great deformity of it. Gummata of the liver are just like gummata elsewhere. They often grow to the size of a tangerine orange, and then they shrink, so that they add greatly to the deformity of the liver. A single gumma is rare; usually two or three are present in the same liver. But it is clear from this description that, although the liver in syphilis may be lumpy and irregular, it is never very greatly enlarged, so considerable enlargement is a sign of malignant disease. The swellings in the liver in malignant disease may alter in size very rapidly; in syphilis the alteration is slow, although it may be quickened by treatment. There is no pain in syphilis unless there is some local perihepatitis over the gumma, and usually there is not. Pain, on the other hand, is common in malignant disease. Although jaundice and ascites have been recorded in syphilitic disease of the liver, and have been associated with either an enlarged gummatous gland or cicatrisation of fibrous tissue in the portal fissure, yet such events are excessively unusual. I can remember no case in point, so the presence of either jaundice or ascites is excessively strong evidence of growth as against syphilis. Then in growth we sometimes get the umbilicus and the gland over the left clavicle enlarged. To complete the picture of syphilitic disease of the liver, it should be added that it is much more often found in the dead-house than it is diagnosed during life, and that the association of lardaceous disease with the scarred and gummatous condition is very uncommon, but when it exists it may cause a very large liver. Unless it is remembered that congenital syphilis may produce exactly the same state of liver as that induced by the acquired disease, mistakes may occur. When this effect of congenital disease is first seen, the patient is nearly always between the ages of 10 and 20 years.

The pericellular cirrhosis of congenital syphilis, which is the cause of a uniform enlargement of the liver in infants, and which occurs in almost 50 per cent. of all the children with congential syphilis, is of much more histological than clinical interest, for it indicates that the congenital syphilis is severe, and many of the infants afflicted die early in life. It is usually not suspected unless the child has some of the ordinary signs of congenital syphilis, and if then the liver is enlarged considering the age, the enlargement is almost certainly due to syphilitic pericellular cirrhosis; but once I have known it to be caused by lardaceous disease

There is not much that calls for special mention about the enlargements due to hydatid or abscess. It is, of course, essential to remember that both lead to a local enlargement of the liver. Growth and syphilis are rarely confined to one part. However, this last summer, a boy, aged about 8, has been under my care for hydatid of the liver, and the organ contained at least three hydatid cysts; but, fortunately for diagnosis, one in the right lobe was so much larger than the rest that the enlargement of the liver was at first local—so much, indeed, that many distinguished members of the profession considered that the child had an enlarged kidney, for the hydatid was in the lower right hand part of the right lobe, and therefore this case illustrated what I pointed out a few minutes ago —namely, the difficulty of telling between an enlarged kidney and the right lobe of the liver. An examination of the blood is of great help in the diagnosis of hydatid, for considerable eosinophilia is present. Ten per cent. of the leucocytes may be eosinophiles; when the hydatid is opened the number of eosinophiles falls quickly. Fluid removed from an exploratory puncture of the right chest should always be boiled to see if any albumen is present. I have known forgetfulness of this lead to a serious result. Some fluid was aspirated from the right chest; it was assumed to be pleuritic. The patient was sent into the country for some weeks. When she came back I put a needle in again, drew off fluid, and found it contained no albumen, and so I concluded it was from a hydatid. Operation disclosed a huge hydatid growing up into the chest from the upper surface of the liver. She succumbed to the operation, but it is quite likely that if she had been operated on earlier she would not have done so. When hydatids or abscesses are small and in the upper surface of the liver, they may be detected if the upper margin of hepatic dulness is very carefully marked out, and a rounded eminence of dulness occurs on the top of the normal line of dulness. I have known this to be no bigger than half a crown, and yet an exploring needle withdrew pus.

As far as my experience goes, the leucocytosis is always considerable in hepatic suppuration, rigors are very common, and both they and the rises of temperature may occur at such regular intervals as to strongly suggest ague. It often requires a very careful physical examination, combined with an examination of the blood, to detect them. I remember a man who used from time to time to get an attack of shivering and rise of temperature. Many doctors saw him; most thought he had influenza; but careful percussion detected the abscess, which was successfully opened.

The next enlargement of the liver we have to consider is that due to cirrhosis. It is usual to describe two varieties—namely, that in which the liver is large —the so-called hypertrophic cirrhosis—and that in which the liver is small—the atrophic; but this is confusing, for there is an extremely rare condition known as hypertrophic biliary cirrhosis, which has nothing to do with ordinary cirrhosis. There is considerable evidence that first the liver in ordinary cirrhosis enlarges, and then becomes smaller. This is what we should expect, for all forms of fibrous tissue tend to contract as time goes on; indeed, cases have been recorded in which cirrhotic livers have become smaller under observation, and Dr. J. A. P. Price, analysing 142 cases of fatal cirrhosis at Guy's Hospital, found that in 80 the weight was over 60 ozs., in 33 the organ weighed between 50 and 60 ozs., and in 29 it was under 50 ozs. These figures show the futility of trying to draw a sharp distinction between hypertrophic and atrophic cirrhosis, for it would be difficult to know where to place the livers between 50 and 60 ozs. in weight, and these figures strongly suggest that the liver is at first larger than normal, for the number of those with a large liver is greater than those with a small, and naturally we should expect the number of patients to lessen as the disease went on, for some would die in the course of it; and that the atrophic livers are only a later stage of the hypertrophic is further borne out by the fact that those with large livers are on the average younger than those with small, and all supposed differences in the symptoms are really due to the fact that certain symptoms are more likely to appear late than early.

Although it is a little outside the title of this paper to do so, I should like to point out that alcoholic cirrhosis is an incorrect name for this disease of the liver, for although the taking of beverages containing alcohol undoubtedly plays an important part in causing the disease in many patients, alcohol cannot be the sole cause, for some patients, notably some children, who suffer from the disease have not taken any alcohol.

It cannot be produced by the administration of alcohol to animals, and in many parts of the world—*e.g.*, Scotland—much alcohol is consumed, but cirrhosis of the liver is rare. It is, I think, undoubtedly commoner among the lower than among the middle and upper classes, and this was the opinion of Sir William Gull and Sir George Burrows. It certainly may exist without any symptoms being present during life. Thus a large cirrhotic liver may be detected in the routine examination for a life insurance, and it is frequently found in the post-mortem room when it has not been suspected during life. The symptoms are well known. Perhaps that least appreciated is the slight pyrexia that may be present; but, speaking generally, this is not so high as it may be in malignant disease of the liver. It may be very difficult during life, and even after death, to tell a cirrhotic from a malignant liver, but facts that will guide us in a local examination are that hobnails are never umbilicated, are never larger than a small cherry, and never become suddenly larger. The irregularity of a liver affected with malignant disease is usually much greater than one which is cirrhosed. Cirrhosis of the liver is often regarded as a local disease of the liver, and it is thought that the pressure of the contracting fibrous tissue on the portal vein leads to the ascites; but this cannot be so, for the fluid in the abdomen usually collects rapidly, sometimes at the rate of a pint a day, which would be very difficult to understand if we believed that the slowly forming fibrous tissue, by its compression of the portal vein, was the sole cause of the ascites. Again, a high degree of cirrhosis may be found in the post-mortem room in cases in which the disease was unsuspected during life, and in which no ascitic fluid existed in the abdomen. Then, again, the amount of ascitic fluid bears no relation to the degree of cirrhosis. It is not most evident when the hæmatemesis suggests that the portal pressure has been high, and it certainly is not due to portal thrombosis, for that is very rare. No obstruction to the portal vein can be demonstrated after death in cases of cirrhosis. It seems to me that the correct view to take is a much wider one, and I believe that, possibly as a result of the damage to the liver, or possibly from some other unknown cause, certain poisons circulate in the blood of a patient with cirrhosis. Possibly they are poisons from the alimentary canal which the cirrhotic liver cannot destroy. If such a poison is a lymphagogue, we have the explanation of the ascites, and also of the œdema of the feet, which is so often seen in cirrhosis. Probably other symptoms are due to the poison, such as the coma and delirium which are seen quite apart from jaundice. The slight pyrexia, wasting and anæmia may in part be due to the same poison. Indeed, unless we believe that such a poison exists, it is difficult to say why cirrhosis should be fatal. The mere cirrhosis of the liver, I would suggest, does not matter much so long as the poison does not get into the circulation, but a person with a cirrhotic liver is at any moment liable to this; then he quickly becomes dangerously ill This view is supported by the fact that when ascites, or coma, or convulsions appear, the patient is, as a rule, within a few weeks of his death, although previously it may not have been known that he is ill. On this view cirrhosis of the liver is like a granular kidney, for a patient may have this for years without knowing it, and then suddenly he becomes uræmic, and is often dead in a few days.

Austin Flint, Watson, Niemeyer, Murchison, Fagge, and many of the older authors taught that the onset of ascites was of very serious moment, for they said if it was much the patient died within a few weeks of its onset. This opinion has been much doubted; so, to investigate the point, I took a number of fatal cases from the records of Guy's Hospital. In ten ascites was present, but the patient was not tapped, but, as far as could be ascertained from the history, the time from first noticing that the abdomen began to enlarge till death was on the average only two months, and the same was true of twelve that were tapped. Dr. Campbell Thomson and others have collected cases from other hospitals which quite support this contention. The onset of swelling of the feet, and the development of nervous symptoms, both also indicate that the end is not very far off.

It is quite impossible, in this brief article, to give a detailed account of that very rare disease, "Hanot's cirrhosis," which has nothing to do with alcohol, occurs chiefly in children, is very slow, and is characterised by the fact that the liver and spleen both become very large. The patient is often stunted in growth, and the fingers may be clubbed Nor can we say much about the form of cirrhosis with a large liver that follows enlargement of the spleen in splenic anæmia, and constitutes Banti's disease. Both this and "Hanot's cirrhosis" are so very rare that they seldom come before any of us. Some observers claim to have produced cirrhosis of the liver by ligature of the bile ducts; but it is doubtful whether this follows if the ligature of the ducts is performed aseptically, and certainly if such a cirrhosis exists in man, it must be quite exceptional, for growths and gall-stones frequently obstruct the duct, and yet no cirrhosis follows. Indeed, most physicians doubt whether there is in medicine such a thing as "obstructive biliary cirrhosis." Malarial cirrhosis has been described, but it does not exist. The mistake of ascribing cirrhosis to malaria has arisen from the fact that many people with malaria have taken more alcohol than they should, and the doctor has kindly wanted to whitewash them, and so has attributed to them malaria cirrhosis which should have been laid to the door of alcohol. It has been said that rickets, diabetes, gout, cancer, tubercle, passive congestion, lead, dyspepsia, and scarlet fever will all give rise to cirrhosis of the liver, but this is a misuse of histological knowledge as applied to clinical medicine. Occasionally, perhaps, a slight increase of fibrous tissue may be detected by the microscope in patients dead of these diseases, but this is never enough to cause the liver to look or feel like a cirrhotic liver; or are the symptoms of cirrhosis ever present. The writings on the subject of cirrhosis are most confusing, but I would suggest that the truth is as follows: There is a common disease—cirrhosis of the liver. No distinction should be drawn between hypertrophic cirrhosis and atrophic cirrhosis, except to express different stages of the same disease. Rare forms of cirrhosis are "Hanot's cirrhosis" and that of Banti's disease. There is a pericellular cirrhosis which often accompanies congenital syphilis. Beyond these conditions there is nothing to which the term cirrhosis of the liver should be applied. Acquired syphilis produces quite a different appearance of hard bands of fibrous tissue with large areas of healthy liver in between.

Simple cysts of the liver, innocent tumours and actinomycosis of it are so rare that we now have only left uniform hepatic enlargements, and, of these, that due to backward venous pressure is the commonest, and is nearly always associated with mitral disease. This nutmeg liver is often larger during life than it appears when cut out of the body, for then much blood has drained out of it. When it is large, the lower edge may reach to the umbilicus, the hepatic enlargement often causes much distress from the feeling of tightness and discomfort of which the patient complains, and it may be that the difficulty of lying down which is so common in heart disease is sometimes due to the direct pressure of the large heavy liver on the heart. If the heart has failed rapidly, the liver is often very painful and tender, and then much benefit follows the application of leeches. In a few cases an expansile distension can be felt synchronous with each beat of the heart, if one hand is placed on the front of the liver and the other behind it. Care must be taken to satisfy oneself that the pulsation is expansile, for the dilated and hypertrophied heart may transmit a jog to the liver at each beat, and sometimes the abdominal aorta will do the same.

The liver is frequently found in the post-mortem room to be fatty, but often this change is associated with cirrhosis, or it does not lead to any enlargement of the organ, and even when it does the patients may be so obese that no enlargement of the liver can be detected during life. Hence fatty liver is not of the clinical importance that might be thought. Nevertheless, the soft enlarged fatty liver may often be detected during life, and successfully diagnosed if any of the many causes that lead to a fatty liver are present. It is of considerable importance to detect it, if possible, for those in whom it can be detected are always in a precarious state of health, and bear operations and serious illness very badly.

The liver is affected in half the cases of lardaceous disease. It may be enormously enlarged, and is smooth and hard. Lardaceous disease often used to follow upon prolonged suppuration, but as surgery does not often allow this nowadays, lardaceous disease is becoming rare. I have seen the lardaceous liver become much smaller after the surgeon drained a chronic abscess connected with the hip. Phthisis and syphilis are much better treated than they were, and therefore, for both medical and surgical reasons, we do not nearly so often see a lardaceous liver as formerly.

The uniform enlargement that follows blocking of the bile duct is only of clinical interest in the few cases in which the presence of jaundice and an enlarged liver leads to a difficulty of diagnosis between malignant disease of the liver and an impacted gall-stone.

I am afraid I have wearied you, and told you nothing which is not common knowledge; but as I said at the beginning, as this is essentially a clinical meeting, my object has been to quickly pass in review such features of enlargement of the liver as are of clinical interest.

Note.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor R. Lepine, M.D., of the Lyons Faculty of Medicine. Subject: "Uræmic Meningitis."***

ORIGINAL PAPERS.

SUDO-KERATOSIS.

By R. W. BRIMACOMBE, M.D.

Assistant Physician to the Skin Department, Kensington General Hospital, and late Pathologist to St. John's Hospital for Diseases of the Skin.

Sudo-Keratosis (Sweat Keratosis) is the name I have given to a disease of the skin, involving the sudoriferous apparatus, and its principal feature is a keratosis of the sweat duct, mainly at its outlet. I have considered it of some importance, because I have not been able to find it in the nomenclature of skin diseases. The accompanying clinical and microscopical diagrams, which I exhibited at a recent meeting of the British Medical Association, clearly indicate:

(*a*) the distribution clinically;

(*b*) microscopically, that the disease is confined almost entirely to the sweat ducts.

The case which came under my notice was that of a boy, æt. 12, belonging to the very poor class. He presented a dirty, ragged appearance, and I have no doubt "dirt" was the principal factor in the origin of this disease.

Clinical.—The dorsal aspect of the hands only were affected, the disease limiting itself to the metacarpal joints (Fig. I.), where no hairs are present. The papules are mostly discrete, slightly raised, with a flattened surface and of a semi-transparent, somewhat hyaline character. The centre of the papule was occupied by a black speck, which gave it a comedo-like appearance.

Microscopical (Fig. II.).—A section of skin (papule) hardened in alcohol, and stained with hæmatoxylin and eosin, shows the lumen of the duct filled up with a plug of nucleated horny cells, hypertrophied and cornified. The lumen is widely dilated, and on each side of it and surrounding it is a layer of hyaline structure without cells. The hyaline structure also pervades the horny cellular mass, and binds the horny cells together. The strata corneum and lucidum are obliterated by the hyaline layer.

At the top of the plug is débris, seen by the naked eye as a black speck, and the plug itself contains masses of deeply-stained wandering cells (polynucleated leucocytes). These cells are minus their nuclei; they have undergone degeneration, become dried up and calcified, and show a diffuse blue staining. Where these cell masses are located, the channel passing through the nucleated horny mass is pressed upon, and consequently becomes blocked up, whilst in the intervening spaces the channel still remains patent.

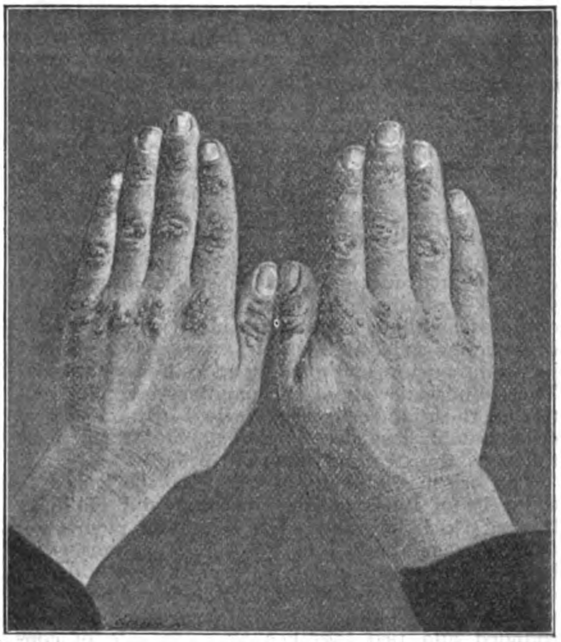

Fig. I.

With Zeiss A Ocular II., the plug appeared to be studded with irregularly-distributed dark pigment granules, and under the oil immersion lens the granules at first led one to think a small micrococcus was present in chains and groups. Further observation, however, showed that they were not pigment granules or micrococci, but free granules without any stain. The sides of the funnel have become partially denuded of their stratum granulosum cells, and the granulated kerato-hyaline cell showed that the supposed pigment granules and micrococci were really the granules remaining from the kerato-hyaline cell, which cells have become dried off, leaving the granules free.

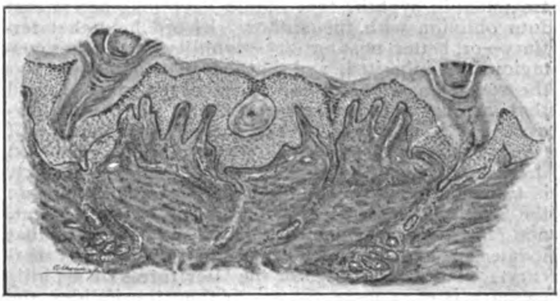

Fig. II.

The stratum granulosum cells on either side of the plug are hypertrophied, except at the lower portion of the plug, where the cells have disappeared and become converted into horny cells, so that the plug comes into actual contact with the stratum mucosum layer. The cells of the latter layer are swollen hyaline, and the nuclei enlarged, with a marked increase in depth of layer, especially around the dilated duct.

The cells of the papillary layer are also enlarged and the papillæ widened, the capillaries surrounding the duct only are dilated with small celled infiltration around.

There is a slight increase of spindle-shaped connective tissue cells in the cutis. Cornification stops in the epidermis, the epithelium of the sweat duct in the cutis is merely swollen, the lumen of the duct moderately dilated and free. There is some slight swelling of the epithelium of the sweat glands, together with dilatation of the lumen.

Owing to the hyaline condition of the epidermis surrounding the duct, although the papillæ are widened, the capillaries dilated, and an inflammatory infiltration is present in the cutis, clinically, these signs are not present, the papules having a pale semi-transparent appearance. An interesting feature in a microscopical specimen is the presence of epithelial giant cells situated on the right side of the dilated duct only, and in a large number of sections examined the left side of the duct was occupied by dilated capillaries and lympathics with small round-celled infiltration, a few sections showing commencing epithelial giant cell degeneration. The cylindrical cells of the papillary layer in relation to the giant cells are lessened in number and development, less deeply stained, and their place taken by the stratum mucosum cells.

The origin of the giant cells may be traced to the cells of the stratum mucosum and papillary layers, which have been left behind or pushed off from the epidermis into the cutis, or, more probably, their development is from the endothelium of the lympathics and capillaries, on whose site they occur. The giant cells are grouped, surrounded and tied together by a capsule of connective tissue cells, and under the low power are seen as a definite hyaline patch.

TREATMENT OF TERTIARY SYPHILIS.

By DR. M. VON ZEISSL,

Professor of Venereal Diseases, Allgemeine Krankenhaus, Vienna.

TRADITION prevails in disease as much as it does in Art. In the therapy of syphilis old-established notions have led practitioners to maintain a rigid course of treatment in syphilis that should have long ago passed into oblivion with the author. Ricord held that tertiary—or, better, post-tertiary—syphilis was neither contagious nor inherited, and that iodide of potassium was the sovereign drug for this form of the disease, and that mercury was injurious, and had no effect whatever. It is now some years since I satisfied myself (1887, I think), by experiments and clinical testimony, that post-syphilis, as well as primary and secondary, is transmissible, and that mercury is as efficacious in the one as the other. Like the trail of the serpent, one class-book after another hands it down to us that iodates act more potently in tertiary syphilis than mercury. This is an error. In the later forms of syphilis mercury is even more efficacious than the iodides, the latter being always more protracted than the former. The mercurial preparations are always more energetic in all forms of syphilis. Like the application of mercury, the diagnosis is often misleading by its peculiar nomenclature. The papules on the iris by many are called gummata, while this is nothing more than a papular syphilide corresponding with those on the body.

This gummatose phenomenon is one of those changes that seems to exhaust itself or become modified by treatment, as it is now seldom met with in Austria and other countries where early treatment prevails. The treatment is usually applied early, and continued energetically for some time after all symptoms of the disease have disappeared, and renewed at a later period if any other symptoms should present themselves.

In Dalmatia, Bosnia, and Russia, at the present day, gummata are common, and are received at hospital every day, while in Vienna you will rarely meet with one. This was not always the case with us, as many of the older physicians know, but it is encouraging to reflect that the hideous morbid changes that used to deface our wards have quite disappeared from our midst.

There is still amongst us a serious result of syphilis that does not exist in Constantinople, where gummata are plentiful. With us disease of the central system is unhappily too frequently the result of the syphilic poison, which is not found in the Orient, no matter how badly neglected the treatment may have been. This is the experience of Glück and Dühring, of Sarajewo and Constantinople. The lecturer saw, while he was in Herzegovina, Bosnia, and Dalmatia, 370 cases of syphilis which he had to treat, and only four out of this great number, which were old cases, had any symptom of either central nerve symptoms or peripheral phenomena. It would seem from these results that worry and abuse of alcohol are necessary for the production of any nerve disturbance in the brain or spinal cord, which may explain the large number of resulting nervous diseases met with in France and other countries, where alcohol is used. Many of these cases are neurasthenic, and doubtless suffered in the past from the forced anti-syphilitic treatment usually practised, where treatment is readily obtained. It is quite possible that this over-treating may do a great deal of harm and no good to the disease, but under the false name of "preventative" it is foolishly resorted to. No such treatment will prevent recurrence, and no treatment should be commenced until undeniable syphilitic phenomena appear. Any other proceeding is injurious. The following may be cited as good examples of the futility of such heroic treatment as preventative:—

G. H. was infected, when 24 years old, in March, 1902. On the first appearance of any syphilitic phenomena, he presented himself at the "Garnison Spital," and there underwent energetic treatment. He received 40 inunctions, 10 rubbings, 3 grammes, ten 4 grammes, and twenty 5 grammes, making a total of 75 grammes of mercurial ointment. During the same period, which extended over two months, he took internally 2 grammes of iodide of sodium. During 1902, 1903, 1904, and 1905 he underwent 30 days' inunction, with a bathing or drinking cure at the Darkau Hydropathic. During this interval of preventative treatment none of the syphilitic phenomena presented themselves, which I can vouch for, having him under my constant observation at the Garnison District, where I was located. The last inunction was given on May 29th, 1905. On June 31st he came to the baths for his annual cure, and told me that he purposed marrying in February, 1906, which I thought a wise proceeding, as the primary examthemata had appeared in 1902, and during the long interval no symptom of syphilis had reappeared. Notwithstanding this satisfaction in my own mind, I asked him to undergo a short mercurial treatment before marriage as a precaution against any recurrence, and on this occasion 30 intra-muscular injections of succinamid of mercury, with internal doses of .05 to 5.00 grammes of the proto-iodide of soda and mercury in pill form. On February 16th, 1906, no sign of lues was to be observed. He returned from his honeymoon on March 21st, and consulted me for an abrasion on the scrotum which had inflamed the cutaneous surface of the penis, where a few weeping papules were observed. The wife had not menstruated since marriage, and complained about March 8th of pain during coitus. On examination, I found in the posterior commisure on the left vaginal wall near the insertion of the labia minora a small infiltration about the size of a hazel nut, which I removed with a knife. The inguinal glands were numerous and swollen, and no doubt remained in my own mind that she had been infected with the syphilitic virus. On April 19th the syphilitic roseola appeared, and I at once prescribed proto-iodide of mercury, 1 gramme, in 50 pills, one to be taken four times a day. At the same time a vaginal douche in the evening, followed by the insertion of a suppository containing 1 gramme of mercurial ointment. The roseola soon disappeared, followed in June by papules on the mucous membrane of the mouth, tongue, etc., upon which I changed the treatment to mercurial vasogen inunction. During the whole of this time she took per-os 1½ grammes of the iodate of soda in pill form, and from the beginning of the pregnancy to the end she took 5 grammes of the proto-iodide internally, 100 suppositories of 1 gramme each, and 80 inunctions of 3 grammes each of mercurial ointment. On November 28th a child was born weighing 3,150 grammes, healthy and strong, and free from every appearance of syphilis. This year, on April 21st, the child weighed 7,000 grammes, and no symptom of syphilis had appeared. The child had been fed on sterilised milk, as it was unwise of the mother to feed it, and equally so for the child to be put to the breast of a healthy nurse. A peculiar symptom should be noted; on the second day after the confinement papules appeared on the tongue of the mother, which again disappeared after a few inunctions while confined to bed.

Here we have a man who has taken every precaution that the science of medicine can suggest to eliminate by mercurial purgation every trace of that syphilitic fiend, even up to the very eve of his marriage, and yet he is able to infect his wife two years after every symptom had disappeared, and, notwithstanding this infection, with energetic mercurial treatment a healthy child is born into the world.

A similar result was obtained in 1905 in the case of a painter whose wife was infected, became pregnant, and was diligently treated with succinamid injection and given iodide, and a healthy child born. The child appeared strong and robust, but in the fourteenth month whooping-cough developed, followed by inflammation of the lung, and it died within 15 days. There is another case demonstrating the fact that we can treat syphilis quite successfully in keeping it suppressed, but we are unable to prevent its occurrence by any protective means we have at our command; but the strange anomaly still exists that if pregnancy intervene a healthy offspring is the result. With these facts before us, it is useless to attempt the impossible in irradicating a poison that will occur in spite of the most persistent treatment. It is therefore better to guide the local symptoms by treating them as they arise with mercurial plasters and iodoform bandages when necessary. When these tertiary results appear on the forehead as periosteal gummata, with fluctuation, antiseptic punctures will often check the formation of abscesses, avoid deformity and a good deal of suffering. When necrosis does occur it is always better to have the loose sequestra extracted. If these be left until Nature throws them off, the health may suffer, and the patient become so much weakened that life may be endangered, but the early interference of the surgeon will avert this result and hasten recovery. In many of these cases free mercurial treatment may modify the gummatose phenomena, and happy results be obtained. In this class of cases the decoction Zittmanni, which is a combination of mercury and sarsaparilla, will be found efficacious. The addition of calomel or other forms of mercury are quite unnecessary if the Zittmanni decoction be made with fresh sarsaparilla, and not with a fluid extract or tincture that has been long prepared. A course of bathing is also a very favourable adjunct in the tertiary treatment where general disturbances of the nerve centres are troublesome. Recurrences in the mouth and throat are readily induced by the abuse of alcohol and tobacco, which should be forbidden in the tertiary form.

It is worthy of remark that orchitis syphilitica seldom passes on to suppuration of the scrotum. If a hydrocele should occur, it will probably spontaneously disappear owing to the disturbance in the vascular system; but when the distention becomes painful it is better to draw the fluid off. As a rule the swelling will recede if the part be enveloped in mercurial ointment in the form of plaster or otherwise. According to the testimony of Levin, bilateral orchitis will lead to oligo- or azoöspermia. In one case of my own, [illegible] destruction of the testis prompted me to [illegible] ni-castration, which the patient would not listen to. The consequence was that one half of the scrotum necrosed, and after four months' treatment cicatrised. A hint might be given to the younger practitioner that the application of mercurial ointment or plasters should be carefully done, as gingivitis or mercurial intoxication may also be induced by this innocent form, and do considerable damage.

Modern treatment has given rise to a number of new preparations, such as sajodin jodalbumose, with the object of making iodine borne easier by the stomach. These are absolutely tasteless, and have the advantage of producing no acne. Iodine catarrh is a troublesome accident producing neuralgia in the trigeminus, which is seldom met with in sajodin or jodalbumose. When the catarrh appears it is better to suppress the iodide in every form at once, and if the soda or potassium iodide have been used, it is better to vary it with the newer class of drugs. In very sensitive cases the pill form is the best, as potassium sodium or iodide, when given in solution, act directly on the mucous membrane, inducing the injury we wish to avoid. Pleurodinia of the left side, and œdema of the glottis and lungs, are also troublesome symptoms of the iodide poisoning, which may frequently be relieved by the addition of 0.03 gramme to 00.5 gramme of quinine to the mixture; this adds to the better digestion of the drug. It is always better to prescribe iodates after meals to relieve the irritation of the stomach, and jodalbumose has been prepared in tablet form, containing 22 per cent. of the drug, to meet this difficulty. This seems to act well, as no increase of the heart's action has been recorded after its use. Iodide acne is another troublesome symptom which readily yields to the combination of cerolin.

Another new drug, named mergal, a mercurial preparation, has recently been introduced in the form of capsules containing 0.05 gramme, and gives excellent results. My own experience is very favourably inclined towards this preparation since its introduction to the Austrian clinic.

PHYSICALLY DEFECTIVE CHILDREN FOR WHOM INSTRUCTION IN SPECIAL SCHOOLS IS NECESSARY. (a)

By REGINALD CHEYNE ELMSLIE, M.S., F.R.C.S.,

Local Assistant Medical Officer to the Education Committee of the London County Council; Assistant Surgeon to the Metropolitan Hospital, London.

It is now eight years since the School Board for London opened the first "Invalid Centre" for the instruction of children who, owing to chronic ill-health or to physical defect, were unfit to mix with their fellows in the larger schools. The number of centres has rapidly increased, until at the present time there are twenty-three open, with accommodation for 1,428 children, and with 1,802 children actually on the roll—a sufficient number to render a survey of these children from the medical standpoint both interesting and instructive.

The schools are dotted about all over London; each accommodates from forty to one hundred children, drawn from a district which may have a radius of one and a half or two miles, ambulances being used to collect the children in the morning and to take them home in the afternoon. A qualified nurse, a cook, and one or more helpers are in attendance at each school; in addition to their other duties they prepare a mid-day meal, for which the children pay. A voluntary association assists in this catering, and also provides food at a reduced rate or free in cases of want.

Children are passed into the school after examination by a medical officer, who also periodically sees all children in attendance. Notes of their histories and of any changes in their condition are kept in a case book. They are required to remain at school until the age of sixteen, unless they are passed to leave or to return to an elementary school at one of the medical officer's visits.

(a) Paper read before the Second International Congress on School Hygiene, London, 1907.

During the past year I have kept careful record of the condition of 1,050 children seen and examined by myself in these schools. As far as possible details as to the disease or deformity from which they suffered, the age at which it arose, the treatment which had been carried out, and the result as shown by the present condition of the child, were noted. With the co-operation of the teachers further notes as to the educational backwardness of the child, the amount of schooling lost through illness, and any notable deviations from the average in ability, were taken.

This number (1,050) represents only a small proportion of the physically defective children in London; but having been taken without selection, we may accept these children as a fair sample of the whole. From a consideration of them I propose to show—

1. What classes of children are at present being educated in the London schools for physically defective children;

2. What purpose is being served by educating these children, what results are being obtained, and generally whether the system is a desirable one.

The general classification of these children is set out in the table. The first point calling for attention is the group of seventy-two children who suffer from none of the conditions for which these schools are primarily intended. This group comprises a small number of semi-blind, semi-deaf children, too bad for education in an ordinary school, too good for a special centre for the blind or deaf, and a larger number of children suffering from no definite illness or defect whatever. The latter were found to be even more backward in their school work than were children suffering from such chronic ailments as tuberculous disease of the hip or spine. They are a group of delicate, nervous children, who have missed much schooling owing to illness; they are unfit to mix with healthy children in a large school, and until the London Education Authority sees its way to the provision of special accommodation for them a certain proportion of them must be found places in the schools for physically defectives.

Turning to the children for whom these schools are more specially intended, it will be seen that just about one half of these are suffering from tuberculous disease of the bones or joints, the hip or spine being the site of the disease in the majority of cases. Indeed, it is for the care and education of those children who suffer from the more severe forms of surgical tuberculosis that these schools may be said to be primarily intended. The age at which these diseases usually arise is of importance. From those cases in which the history had been recorded the following facts were made out:—

In tuberculous disease of the spine the disease arose between the ages of one and five in 72 per cent.

In tuberculous disease of the hip the disease arose between the ages of two and six in 64 per cent.

In tuberculous disease of the knee and of other joints the incidence was spread equally over the first nine years.

These facts agree with such statistics as have been published from the records of hospitals. They indicate one great difficulty which is bound to arise in dealing with these children in schools, viz., that the disease is already well established, and much deformity has often arisen, long before school age is reached. For example, of the children with disease of the spine who were examined, in only about 10—15 per cent. was the disease considered to be active, whilst 58 per cent. had very severe fixed deformity of the spine.

Many of the observations made upon these children are of purely surgical interest; some, however, also bear very directly on education. In the first place, the actual mortality from the disease is not high, but a considerable proportion die from intercurrent affections. We may take it, however, that the majority of the children will live to adult life, will then outgrow the actual disease, but be left with the deformity to which it has given rise. They will then have to take their place in the world, and to endeavour to earn their livings in competition with others who do not suffer under the disabilities of a fixed deformity, and of educational backwardness, the result of prolonged ill-health. Surely, then, our endeavour should be at one and the same time to prevent or alleviate deformity, and to carry on instruction during the periods of illness.

Now, in examining a series of cases of quiescent tuberculous disease two points stand out at once. The first is the frequency with which disease which was apparently cured reappears. A great physician has said of tubercle in the lungs that it is often arrested, very rarely cured. The same is true of tubercle in the bones and joints; over and over again a child with hip disease remains apparently cured for a year or two, then some slight accident, a little over-exertion, or some affection of the general health lights up the disease afresh, and treatment has to be carried out all over again. For this reason I am convinced that this class of children should be kept out of the large schools, no matter how well they appear to be. To allow them to mix commonly with their healthy fellows, to play rough games without supervision, frequently ends in disaster.

The second noticeable fact is the large proportion of these children who are left, when the disease is arrested or cured, with a severe deformity which seriously affects their prospects in after-life. Now this is not unavoidable; fully half the deformities following on tuberculous disease are due to three causes which may be overcome. The first is the commencement of treatment at too late a stage; this is remediable to a certain extent by increasing medical inspection, and by training those having charge of small children to consider any weakness of the spine or limbs as serious. The second is too short a period of rest in recumbency during the active stage of the disease; and the third, I regret to have to say it, is meddlesome operative surgery. These last two are not by any means altogether the fault of the surgeons. Owing to the absence of special accommodation for these children most of them have to be treated at the large general hospitals. Here there is a constant pressure upon the beds; there are always more patients waiting for admission than it is possible to find room for in a reasonable time. Moreover, some of the central hospital funds base their grants to hospitals upon the average length of stay of the patients; so that the latter have to be discharged at the earliest possible moment. This rule may be considered necessary to prevent abuse, but it certainly is not in the interests of the patients, and it is particularly bad in its effect on the treatment of children with tuberculous bone disease. They are taken in during some acute exacerbation of the disease, or for an operation, are discharged as soon as possible in a walking splint with crutches, and are then seen at intervals as out-patients. It would be almost impossible to conceive a more thoroughly bad method of treating them.

One result of this method is that children are constantly being taken to a fresh hospital, the parents are dissatisfied with the progress, or perhaps, having stayed away from the out-patient department too long, are afraid of receiving a scolding on returning. Meddlesome operation can be traced to the same causes. The operations to which I specially refer are excisions of the hip and knee joints; these have the advantage that they sometimes cure the actual disease right away by removing all the diseased structures. The surgeon, knowing this, and encouraged by the success of bold operating in other lines, seizes the opportunity of curing the patient after only a brief stay in hospital. The ultimate result several years after is seen probably at another hospital by another surgeon, who ascribes it to a bad operation, and never suspects that many of the excisions that he himself has done have turned out every bit as badly. Among the cases of old hip disease seen by me, twenty-five had been subjected to excision, and in every one of these a weak, flabby joint was left, the functional result being in every case bad. Similarly of thirty-four children on whom excision of the knee had been performed, twenty-nine were left with a severe deformity. I have no wish to condemn these operations entirely; in their proper place they both are of use, but if they are indiscriminately employed in an attempt to arrest the disease rapidly, not only are they often unsuccessful in this object, but also they often lead in the end to a crippled and useless limb.

The second group of cases includes children suffering from various congenital or acquired deformities, the latter chiefly the result of severe rickets, from infantile paralysis, and from spastic paralysis. These have the characteristic in common that the disability is of a fixed nature; it may in some cases be improved by surgical treatment, but it will not become worse as age advances. These conditions also are either present at birth, or arise in the first two or three years of life. Only the more severe cases of such deformities and paralyses require education in special schools; in the slighter cases the children are quite fit to mix with their healthy fellows. The requirements of this class of children are (1) constant medical supervision during the years of growth, to ensure that they are so treated as to leave them under the least possible disadvantage; (2) special education to fit them for the special work which their crippled condition will necessitate.

The third class includes children with heart disease, with progressive forms of paralysis, and with epilepsy, chorea and some other chronic illnesses. These are alike in that many of them will never reach adult life at all, whilst those who do will as a rule not be fit for any form of manual labour. Their requirements are similar to those of the last class.

Having shown what children are being educated in the London schools for physically defective children, let us consider what the present methods of work are accomplishing. These schools may aim at one or other of two objects:—

1. Simply to educate the children as far as possible, then to turn them out into the world ignoring their physical defect.

2. To do the utmost to arrest, alleviate or improve the physical defect, and by improving the child both educationally and physically to place him in such a position that he is able to support himself.

In London at present it is the first of these policies that is adopted, certain additions to it, however, being made. The additions are:—

1. Supervision in school by a nurse and a doctor, and occasional recommendation of treatment.

2. The provision of good food.

3. Voluntary aid by the local charitable societies, which as a rule keep in touch with the children in school through the managers.

4. Assistance in finding suitable work after leaving schools through the after-care committees.

These are all very good so far as they go, but those who assist in carrying them out would, I am sure, be the first to admit that the results are most unsatisfactory. In the first place, the work is voluntary, is not always systematic, and is carried out by energetic people, who mean well and work hard, but too often have an insufficient technical knowledge, and have no one upon whom they can fall back for advice and assistance. In the second place, we have no power over the careless, improvident parents, who are too lazy or too neglectful to make an effort on behalf of their own children, and who, perhaps, object to the offer of the after-care committee to get their boy apprenticed, because it means that they will lose the immediate return they might get from his wages as an errand boy, or in some similar occupation.

The problem of finding suitable work is rendered more difficult by the backwardness of the children, nearly all of whom are two standards behind their proper position, and many a great deal more than this. Moreover, the special nature of the work required is a further difficulty; the estimate arrived at upon this point was that only 20 per cent. of these children will be able to earn their living at any ordinary form of occupation, 50 per cent. will be able to work if special skilled work is found for them, the other 30 per cent. will either not live, or will be totally unfit to support themselves in any way whatever.

Practically, then, although much good is done in individual cases, in London at present a large number of these children are turned out into the world at fifteen or sixteen to make their way as best they can, their physical defect being ignored. And although it may be said that the education authority has done its duty in educating them, the community at large must be the poorer by having a number of physically unfit individuals left upon its hands. Without entering into particulars of alternative schemes for dealing with the problem, certain essential points which should be provided for in such schemes may be named.

1. Three classes of children must be provided for:—

(*a*) Children with tuberculous disease of the bones and joints.

(*b*) Children with fixed deformities and paralyses.

(*c*) Children with diseases of the heart, lungs, etc., of a chronic nature.

2. For children of the first class treatment at the earliest possible time after the disease shows itself is essential, and as these conditions arise early in life, provision must be made for quite young children.

3. Whether the institutions provided are called hospitals or schools is immaterial; they must serve both purposes.

4. Technical instruction is essential for the older children.

5. For certain cases the provision of a permanent home is desirable.

EXAMINATION OF 1,050 CHILDREN IN LONDON SCHOOLS FOR PHYSICALLY DEFECTIVES.

I.—Children for whom Instruction in Special Schools is necessary on Account of the Physical Defect.

	Boys.	Girls.	Total.		
A.—Tuberculous Disease of					978
1. Spine	106	80	186	480 (about 50 %)	
2. Hip	100	95	195		
3. Knee	46	34	80		
4. Other Bones or Joints	8	11	19		
B.—Fixed Deformities or Paralyses.					
5. Various Deformities	66	71	137	315 (about 30%)	
6. Infantile Paralysis ...	57	57	114		
7. Spastic Paralyses ...	27	37	64		
C.—Various Diseases.					
8. Heart Disease ...	61	59	120	183 (about 20%)	
9. Progressive Paralyses	8	1	9		
10. Various	22	32	54		

II.—Children for whom Instruction in Special Schools is not necessary on Account of the Physical Defect.

	Boys.	Girls.	Total.	
D.—Defects of Eye or Ear only	9	8	17	72
E.—Without Special Defect...	26	29	55	
Totals	536	514	1,050	

Children with more than one physical defect were included under that defect which was considered to be the most serious.

THE OUT-PATIENTS' ROOM.

THROAT HOSPITAL, GOLDEN SQUARE.

Foreign Body in the Nose.

By **Frank Rose**, M.B., F.R.C.S.

Among the out-patients was a little girl, æt. about 5, who had been brought by her mother on account of a discharge from the right side of the nose which had been noticed for about a fortnight; there had occasionally been a little blood with it. The mother did not know the cause, but seemed inclined to attribute the trouble to a blow which she vaguely intimated the child had had in the playground. On examination, a thin and purulent discharge was seen issuing from the right nostril; the upper lip on the same side was red and excoriated. Mr. Rose pointed out that the case was certainly either one of membranous rhinitis or foreign body in the nose; sinus suppuration was excluded by the child's age. Membranous rhinitis, though possible, was unlikely, he said, because it nearly always attacked both sides of the nose, though occasionally it was unilateral. Therefore, the only probable diagnosis was that of a foreign body. On suggesting to the mother that some foreign body had been introduced into the nose, she denied the possibility. After wiping away the discharge from the anterior part of the nose, a dark green body became visible. A blunt hook was then passed in behind this body, and a boot button was brought out, much to the astonishment of the patient's mother. Mr. Rose laid stress on two points. (1) That a purulent unilateral discharge, mixed with blood, from the nose of a young child nearly always indicated a foreign body; if the discharge were offensive as well, then the diagnosis of a foreign body was almost certain. (2) In removing these foreign bodies, much the best method is to employ a blunt hook, and not forceps, as forceps are apt to push the foreign body further and further into the nose, whereas the blunt hook gets beyond the foreign body and at once pulls it down. This, of course, would apply to round, hard objects, such as buttons, beads, etc., which are the objects commonly found in children's noses.

Foreign Body in the Larynx.

A girl, æt. 19, came among the out-patients with the following history: Two days previously, when taking broth at supper, she felt something stick in her throat, and had a severe attack of choking. She went to visit a doctor, who passed a bougie down the œsophagus without giving the patient any relief. It was then noticed that she had almost completely lost her voice. She was able to swallow water and take some toast. On the next day she again had medical advice, but no relief was obtained, although an emetic was given. A foreign body was discovered by the medical man, who then recommended her applying at the hospital for its removal. On examination the patient was noticed to be in no discomfort whatever. The breathing was natural, there was no cough, and it was only when the girl began to speak that anything wrong was detected. Her voice was very weak and slightly husky. On inspection of the larynx it was seen that there was a foreign body lying inside the larynx in contact with the posterior wall; a white spot was also visible on the anterior wall of the trachea below the vocal cords. The whole larynx was reddened. The pharynx and larynx were painted with cocaine until they were anæsthetic, and the foreign body was extracted with Krause's forceps without any difficulty. It proved to be part of the breast-bone of a chicken. It was a thin plate of bone, triangular in shape, measuring one inch vertically, its horizontal base being a little more than three-quarters of an inch. It had been situated in the larynx as a vertical plane, so as to form a sort of median partition; its median upright position explained why the breathing had not been impeded.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Pelvic and Subphrenic Abscess.—Mr. Arthur Edmunds operated on an unmarried girl, æt. 20, who ten days previously had been seized with an acute pain in the epigastrium while she was at work. She was compelled to go home and lie up, but the pain was not excessive, and there was no definite collapse. During the ten days preceding her admission into hospital, her symptoms were equivocal; the pain continued with remissions, and the abdomen became gradually distended; there was a slight temperature, and the pulse was quickened. The abdomen at first was generally tender, but for two days before admission the tenderness had become restricted to the hypogastric region. On admission she was seen to be well nourished; her pulse was rapid—about 120; her temperature was about 102°; her tongue was furred. On examining the abdomen, a large swelling could be felt, extending upwards from the symphisis, but not extending into either flank. The abdomen, as a whole, moved poorly with respiration, and was moderately distended. Per vaginam a swelling could be felt bulging into Douglas's pouch. It was obvious that the case was one of intra-abdominal abscess, and the diagnosis, Mr. Edmunds said, lay between three groups of causes: In the first place one naturally considered the possibility of the abscess being due to appendicitis. Here it seemed probable that the appendix was not at fault, for although the pelvic swelling was a very large one, there was not the slightest resistance in the right iliac fossa, and there was no definite tenderness about the root of the appendix. It was also a very marked feature in the case that the pain had commenced in the upper part of the abdomen, and had never concentrated itself on the appendicular region. There was no history of previous attacks, so that, on the whole, it was probable that the appendix was not affected. The diagnosis then lay between a pelvic abscess which had been produced in or around a pelvic viscus, and one which had been infected from a distant organ. The pelvic origin of the abscess was not very easy to understand in view of the intact condition of the vaginal outlet, and taking into account the point of origin of the pain, it seemed probable that the source of the trouble was to be sought elsewhere. In giving an account of her history, the patient had mentioned that she had had occasional vomiting, but it was only later in the case that one was enabled to elicit the fact that she had had slight hæmatemesis. The abdomen was opened in the middle line so as to explore the swelling from above, and it was then found that there was very little wrong with the appendix or any other intra-abdominal organ. Towards the pelvis, however, the intestines were matted together to form the roof of a large fluid swelling, obviously a big abscess. The question now arose as to the best method of draining this. Although it is quite easy, Mr. Edmunds pointed out to drain an abscess across the peritoneal cavity it is by no means desirable to do so when the abscess is so large that any opening into it will be very likely to flood the whole peritoneal cavity with pus. While it is quite easy to sponge up a few drachms of pus in a deep abscess, it is impossible to do so when the contents of that abscess can be measured in pints, and it is much safer to drain through the vagina. Accordingly, the index finger of the right hand was passed into the vagina with a pair of scissors lying flat along its palmar surface, and with some little difficulty the posterior cul-de-sac was opened up. The left hand was kept in the abdominal cavity, so as to form a guide to the forceps, which were afterwards passed up the opening made by the scissors. The blades of the forceps were then separated so as to enlarge the opening, and a large drainage tube inserted, the end of which dipped beneath the surface of a bottle of carbolic lotion. The abdomen was then closed by through and through sutures of silkworm gut, this part of the operation being entrusted to an assistant whose hands had not been soiled by the pus which escaped from the pelvic abscess. The tube acted well, and the abdominal wound healed kindly. The pain was relieved, and the patient's condition improved. In the middle of the third week after the operation, however, she began to have cough and pain in the left hypochondrium, which was made worse by any movement or by drawing a long breath. Signs of fluid manifested themselves, and a needle was put into the chest, with the result that pus was obtained. Accordingly, a portion of the eighth rib was excised and the pleural cavity opened, giving vent to about a pint of clear, serous fluid. On further exploration the diaphragm was found to be pushed up rigid and immovable; this was obviously due to a collection of pus beneath it. It seemed necessary, in view of the infective nature of the case, to drain the pleural cavity as well as the subphrenic abscess. A further portion of rib extending almost down to the costal cartilage was removed, and the wound was divided into two by suturing the diaphragm to the chest wall, and by drawing the muscles together around a drainage tube, which was inserted into the pleura. An opening was then made into the diaphragm from above, about an ounce of pus let out, and a drainage tube passed into the abscess cavity. The patient stood the operation well, and is now making very good progress. The vaginal discharge has almost ceased, and the wounds in the chest wall are healing rapidly. Mr. Edmunds said that in treating such abscesses various methods could be employed, the ideal one being to suture the diaphragm to the chest wall, allowing the pleural cavity to become shut off before opening the abscess cavity, but in the present case it was not possible to do this on account of the large amount of fluid present; and, furthermore, the probable infective nature of the pleural contents made it desirable to drain this cavity, a method of procedure which has the disadvantage of exposing the patient to the risk of further infection from the subphrenic abscess—a risk which, in the present case, has fortunately not been realised.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

First Meeting held on Friday, October 11th.

Sir Thomas Barlow, President of the Section, in the Chair.

Mr. T. H. **Openshaw** showed a case of Congenital Absence of the Fibula in a boy, æt. 10. The outer half of the foot and the outer two toes were also missing on the same side. There was no similar case in the family. By means of suitable apparatus the boy was able to walk perfectly and to play games. Mr. Openshaw also showed a child six months old in whom both tibiæ were practically absent. He thought that the scar so often present in these cases was due to intra-uterine fracture of the bone. He advised against amputation of legs with this deformity.

Mr. **Douglas Drew** showed a girl in whom, after two arthrectomies for tuberculous disease of the knee, a movable joint had resulted.

Mr. **Drew** also showed a case of Congenital Dislocation of the Patella, which had been cured by operation.

Dr. A. E. **Garrod** showed a woman, æt. 25, who presented multiple nodules of rheumatic origin. She had had rheumatic fever two years previously, but there was no cardiac lesion. The nodules had been present for eighteen months, but had softened somewhat after the use of Bier's treatment; they were present over the metacarpo-phalangeal joints, elbows, and knees of both sides and over one shoulder. Dr. Samuel West had seen several similar cases, and in some, even the worst, there had been no heart lesion present. Sir Dyce Duckworth was familiar with such cases in adults, and had been struck by their long duration. Dr. Bertram Abrahams had seen four cases in adults, and was sceptical about their being always of a rheumatic nature; in some he had followed for years no rheumatic manifestations had developed. He pointed out the remarkable symmetry of the nodules in adult cases, and their greater discreteness. Dr. Poynton had seen in children nodules of long duration. The President agreed with Dr. Garrod's diagnosis. He had found the association between nodules and endocarditis less close in adults than in children. They often lasted over a year in adults.

Mr. F. J. **Steward** showed a child that had recovered after operation for pyopericardium. An empyema had previously been opened at the left base, and the pericardium was opened and drained through this wound. The pus of both was pneumococcal. Dr. West had seen recovery from an anterior opening. He advocated simple incision without thoracotomy. Mr. R. T. Godlee related a case in which Mr. Raymond Johnson had successfully drained a pyopericardium that was secondary to osteomyelitis.

Mr. T. **Hutchinson**, jun., showed a case of Fusiform Aneurism of the Right Carotid Artery in a woman, æt. 63. There was no syphilitic history. Symptoms dated back for 18 months. He proposed to perform distal ligature, as it was impossible to perform this proximally.

Dr. F. E. **Batten** demonstrated a case probably of Cerebellar Atrophy. The patient, a man of 62, had had slight unsteadiness for six years, but had become much worse after an attack three years ago. There was slight nystagmus and marked kinetic ataxy. In the lower limbs the ataxy was chiefly present on walking.

Dr. H. A. **Lediard** showed the case of a man with Diffuse Sarcoma of the Skin. This was most marked in the head, but extended in the trunk to the waist. Sir Dyce Duckworth did not agree with the diagnosis, and advocated treatment by large doses of sarsaparilla.

Mr. **Cecil Rowntree** showed a male patient with a large, probably Myxo-sarcomatous, Growth on the right thigh.

The **President** then delivered his introductory address, in which he reviewed the history and work of the Clinical Society for the forty years of its existence.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 13th, 1907.

Dilatation of the Stomach.

Dilatation of the stomach is one of the most troublesome affections that a practitioner has to deal with. The treatment is medical, but, above all, dietetic. A proper régime imposed on the patient is of the greatest importance, for without attention to the nature of the food medicine can have but an illusory effect.

The meals should be so arranged that food should not be introduced into the stomach unless the preceding repast has had time to digest. In some cases, says Prof. Lemoine, the organ is very sluggish, so that only two repasts daily can be allowed, one at 10 o'clock in the morning, the other at 7 in the evening. Generally three repasts may be taken, and no drink or food allowed between the meals.

The dry régime is best suited for these patients, as liquids distend the stomach; for the same reason soups should not be absorbed.

The first repast in the morning should consist of tapioca, or one or two boiled eggs with a piece of bread. The two other repasts may be varied in their composition, but vinegar, sauces and grease should be avoided, as well as fresh bread. The solid food may be composed of rice, tapioca, macaroni, roast meat, salmon, fresh cod, vegetables (well cooked); marmalades, jams, all kinds of game, shell-fish, and strong cheese should be excluded.

The medical treatment should have in view the maintenance of the energy of the muscular system. As a nervine tonic, phosphate of soda is of a great value if persevered in for several months:

Phosphate of soda, 4 dr.
Tincture of nux vomica, 40 m.
Syrup of bitter orange, 10 oz.
A tablespoonful an hour before meals

Or, Sulphate of strychnine, 1 gr.
Water, 5 oz.

A teaspoonful in a little water before each meal.

Ipecacuanha in small doses is an excellent stimulant; one-grain pill after meals has been recommended by Mathieu.

Massage of the epigastrium has been practised by Dujardin-Baumetz, and with good results, but it requires to be done methodically, and according to precise rules, and by practised hands. However, it can be replaced by a general massage done each morning in a bathing establishment after a cold douche. When the patients cannot take the shower bath, it can be replaced by rubbing the whole body with a flannel moistened with a mixture of alcohol and turpentine:

Spirits of turpentine, 2 dr.
Spirits of camphor, 4 oz.
Spirits of lavender, 2 oz.

And an alkaline bath twice a week:

Carbonate of soda, 4 oz.
Salt, 2 lb.
(For one bath.)

Washing out of the stomach should be reserved for cases where the distension is considerable, and symptoms of putridity of the contents of the stomach exist.

The food that remains incompletely digested in the stomach accumulates after each meal, and finally undergoes fermentation, provokes the formation of ptomaines, and becomes dangerous for the economy. It is to the absorption of these toxins that may be attributed headaches, vertigo, neuralgia, hepatic colic, etc. In such cases antiseptics are plainly indicated—salicylate of bismuth, salol, betol, naphtol, or benzonaphtol. Laxatives in the form of purgative mineral waters (Montmirail, Châtel Guyon, Rubinat) should be ordered two or three times a week.

Besides the above treatment, the patients should be enjoined to suspend all intellectual work and replace it by physical exercise, manual labour, fencing, gymnastics, bicycle riding, etc.

INJECTIONS OF THIOSINAMIN.

Within the last few months the virtues of thiosinamin are being spoken of after many years, during which it had fallen into oblivion. It is now being employed in sclerous affections, such as pleuretic adhesions, chronic perigastritis, stricture of the urethra, the œsophagus, and the affections of the middle ear (sclerosis of the tympanum).

Two patients were recently treated for stenosis of the pylorus following gastric ulcer. Every three days 20 drops of a solution of thiosinamin (1/10) were injected. At the end of three weeks considerable improvement took place. In another case of ankylosis of the knee, mobility was restored by daily injections of the same solution, to which was added salicylate of soda.

GERMANY.

Berlin, Oct. 13th, 1907.

AT the Free Society of Surgeons, Hr. Nordmann showed a case of

INTRAPERITONEAL RUPTURE OF THE BLADDER.

A waiter was wounded whilst in a state of drunkenness. He had a constant desire to pass urine, and in the course of 24 hours showed signs of peritonitis. A catheter was passed, and a large quanitity of urine drawn off, which was afterwards found to come from the peritoneal cavity. He concluded that the case was one of perforated gastric ulcer, and made an opening into the upper part of the abdomen, but found that the stomach was whole. He then opened the lower part, and found a rupture of the bladder. The parts were united without drainage, and recovery took place.

Hr. Martens spoke on the technique of

OPERATIONS FOR PERFORATED ULCERS OF THE STOMACH.

He felt himself bound, he said, in cases of perforation peritonitis, when too much time had not elapsed, to open the abdomen, whether ulcer of the stomach with perforation could be diagnosed or not. It did not do to wait for the shock. The patients were given saline infusions, and were operated on under general narcosis.

At the operation the aim should be to find the perforation as quickly as possible, and close it. It was enough to stitch it over; at the most the edges might be freshened. Omentum was adjusted over the sutures. It was only advisable to add gastroenterostomy if the ulcer was situated on the pylorus, and this was narrowed by the sutures. It only became a question of jejunostomy when the ulcer was very large, and it could not be closed by the sutures.

After completing the suture the abdomen was thoroughly washed out with saline solution, of which 20 to 30 litres were made use of. He kept on with the washing out until all stomach contents were washed out.

The abdomen was closed up to a small opening for drainage, but no tampon was left in. He had had the leucocytes counted in his cases, but the results obtained were not constant.

Hr. Federmann, on the other hand, laid stress on the counting of the leucocytes both for diagnostic and prognostic purposes, and thought it advisable to leave out the washing out of the abdomen.

Hr. Körte was of opinion that early diagnosis was easier than after 15 to 20 hours, when the peritonitis had become fully developed, and the whole abdomen equally tender. He had now operated in 20 cases, of which 6 had died. The prognosis was not so unfavourable if the operation was performed within the first 24 hours. Washing out was unconditionally to be recommended. It was, without doubt, the most non-irritating way of cleaning out the abdomen. After that it was best to close up entirely. It was to the purpose also to add gastroenterostomy to the closure of the ulcer.

Hr. Martens related three cases of

PYLEPHLEBITIS COMPLICATING PERITYPHLITIS.

One of the cases was remarkable in that thrombosis of the portal vein occurred, although the appendix was removed within 40 hours of the commencement of the attack. In general, however, pylephlebitis was more rare since the introduction of early operation.

Hr. Körte confirmed what had been said, and had seen a case in which the patient died of pylephlebitis, although the operation was performed within the first 24 hours.

Hr. Israel had seen a patient who from an error of diet had a rigor, and died in three weeks from constantly recurring rigors, jaundice and swelling of the liver. The autopsy revealed multiple abscesses of the liver, pylephlebitis, a quite small ulcer on the vermiform appendix, and at the base of it a thrombosed vessel.

Hr. Engelmann showed a patient with

ACUTE INFLAMMATION OF THE PANCREAS.

He was admitted into hospital with symptoms of general peritonitis, great tenderness over the upper part of the abdomen, which projected forwards, and showed dulness on percussion. Recovery took place after clearing out the exudate and drainage of the bursa omentalis. The next case was one of rupture of the liver from compression. The torn part was united by suture. Some time afterwards a subphrenic abscess formed, which was opened. Recovery took place.

AUSTRIA.

Vienna, Oct. 13th, 1907.

POLYNEURITIS AND BACTERIUM COLI.

CHOROSCHKE has been devoting his attention to parenchymatous and interstitial polyneuritis, and finds that many parenchymatous cases have clinically every appearance of interstitiæ. The absence of fever and the long-continued course of the disease declare it to be a toxæmia. Whence comes the infection? he asks; and answers—from the bowel; it makes its way into the urinary tract, which he considers the most favourable for its transmission. The narrowing of the lumen of the bowel, which produces a coprostasis higher up from the poison of the bacterium coli, which wanders from the bowel through the atrophied gastric wall, and thus makes its way to the bladder by the peritoneum, in which red stripes can be traced in the post-mortem room, clearly demonstrates the mode of passage. In consequence of the long retention of the fæces in the bowel, the bacterium becomes more virulent, and thus easier cultivated in the urinary tract, where any slight lesion admits of a ready absorption into the blood. This he considers the real cause of so many cases of meningitis and myelitis being associated with the bacterium coli, and from this attack on the meninges reasons that coprostasis produces polyneuritis, from which the toxin of the bacterium can equally be obtained with the same readiness.

ATOXYL IN RELAPSING FEVER.

Glaubermann has been using atoxyl for some time with the best results, but it must be given in larger doses than the prescribed orthodox quantity. He treated 30 cases with small doses, but did not obtain the effects expected. He tried 40 other cases with doses of 9.0 to 23.0 cubic centimetres of a 20 per cent. solution. In seven to fourteen days the fever disappeared.

He considers this a reliable drug in relapsing fever, shortening the pyrexia by three days.

Origin of Cancer.

At the "Naturforscher," Prof. Kelling again advanced his theory of the origin of cancer by the implantation of embryonic cells, which he considers are taken in as foreign bodies in the nutrition, and under certain conditions are absorbed through slight lesions in the mucous membrane. As further proof he exhibited the blood serum test in carcinomatous patients. This is conducted with the albumin of the foreign embryonic cells, where the mixture produces a cloudy condition, or in others a rapid solution of the blood corpuscles. In 265 experiments half of them were positive, while 28 of these reactions positively negatived the diagnosis of cancer, and which were operated on with perfect success. He disputed Dungern's results on the ground of absent control experiments.

Curious Crystal.

At the same meeting Dr. Mayenburg exhibited a gigantic crystal of the chromate of alum which he had grown from the size of a pin's head to half a metre in the course of 24 years. The small crystal he commenced with was kept in a saturated solution, cold, of the same substance, and throughout its growth retained a beautiful octahedral form. The crystal weighed 42.5 kilogrammes, or 85 lbs.

Female Structure.

Prof. Schultze, in his anthropological research, affirms that the female in structure is more child than man, and refers to the plastic form of the skeleton and the formation of the muscular, fatty, and pigmentary parts, as well as the proportion of the face. The legs are relatively short, while the body is large. He maintains that the greatest disproportion exists in the head and body, the female brain being absolutely lighter, while the child's is relatively heavier than the male. The finer skeleton of the face, the form of the lower maxilla, and the simplicity of the cerebral surface, are distinguishing features of the female. The smallness of the throat and greater size of the thyroid, lung, heart, liver and spleen, with different construction of blood and stomach, are other adjuncts. The cause of this juvenile condition is not due to any depression by the male, want of culture, etc., but is rather due to the phylogenetic progression of the male.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Teaching of Clinical Surgery in Edinburgh.—A scheme for the improvement of the teaching of clinical surgery in the University of Edinburgh has been promulgated by the University Court, and will probably come into speedy operation. It is proposed that the ordinary surgeons to the Infirmary, except the surgeon teaching women students, be invited to become University lecturers on clinical surgery, on condition that—(1) Each lecturer acts as an examiner on the same terms as the professor of clinical surgery. (2) As in the case of other lectureships, 75 per cent. of the fees to be paid to the lecturer. (3) The University Court provides a sum to each lecturer which will cover the salary of a clinical tutor. At present the students divide themselves unequally among the different teachers of surgery, and one of the circumstances which influences the distribution is the fact that only one of the surgeons, as a rule, is an examiner. Not unnaturally, this leads to his clinic being unduly crowded, and prevents the whole clinical material of the hospital being used to the best advantage. The plan of the Court is a simple way of remedying this, and it is to be hoped that it will be accepted by the ordinary surgeons. If it comes into force it will also have the advantage of shortening the period over which the examination in clinical surgery extends. Each lecturer will, of course, receive the whole fees of the extramural students attending his class, as well as the proportion of the fees of University students.

Edinburgh Royal Infirmary.—Retirement of Dr. Alex. James and Mr. Chas. McGillivray.—At the usual weekly meeting of the Board, a resolution in appreciation of the services of Dr. Alexander James was passed by the managers. They "fully realise, and highly appreciate, the assiduous and constant attention he has paid to the patients under his care, and the great success which has attended his labours, and they are well aware that his skill as a teacher of clinical medicine has been shown by the large number of students who have taken advantage of his instruction in the wards under his care. By his kindly and considerate manner to all with whom he came in contact, by his great ability, and by his unwearied devotion to duty, he has endeared himself to his patients, his students, and his colleagues. In parting with Dr. James, the managers offer him their heartiest good wishes, and as a testimony of their esteem for him, appoint him one of the consulting physicians to the Institution." A similar recognition was paid to Mr. C. W. McGillivray for his services as one of the acting surgeons for the past fifteen years. The managers appointed him one of the consulting surgeons of the Institution.

New Physical Laboratory, Edinburgh University.—At the beginning of the winter session, next Tuesday, the physical laboratory will be transferred to the new buildings, which consist of the reconstructed surgical hospital of the old infirmary. The main walls of the building have been retained, but the wooden flooring has been replaced by concrete on steel girders, running east to west to avoid magnetic disturbances. On the principal floor is the lecture-room, a library, and a reading-room. The arrangements for demonstrating experiments during lectures are very complete. Under the lecture table there is a room for manipulating boilers, gasometers, and other bulky pieces of apparatus, and the blackboards, etc., slide down into this room. The lantern is set in a gap in the lecture table, and its rays are reflected by a mirror on to a screen which is equally visible to all the students. Above the ceiling over the lecture table is an attic, the floor of which has openings for experiments with long pendulums, falling bodies, etc., and a drop of 45 ft. can be obtained. The whole department has been reconstructed by Sir Rowand Anderson and Mr. Balfour Paul, architects. They have been advised by Professor Macgregor, who has made a careful study of the most recent and complete laboratories on the Continent and in America.

Consumptive Sanatorium for Ayrshire.—As a result of a conference between the various local authorities in the county, the Chairman of the Glenafton Consumption Sanatorium has offered to hand over the sanatorium to the county as a free gift provided the county give opportunities for treatment at least as great as the Ayrshire Association does at present. A report to the Ayr District Committee from Dr. Macdonald showed that to meet the county's needs there would require to be provided 80 beds, which would involve the enlargement of the present sanatorium at a cost of £6,000, and a subsequent charge for maintenance of about £3,600. It was agreed to send down this information to the various local bodies concerned.

Complimentary Dinner to Dr. MacPhail, Glasgow.—The occasion of this function was the departure of Dr. MacPhail from St. Mungo's College to take up the post of Lecturer on Anatomy at Charing Cross Hospital. Professor Cleland presided over a large gathering, and the toast of the evening was proposed by Dr. Gemmell, and afterwards Sir John Ure Primrose presented Dr. MacPhail with a chronometer, a dissecting microscope, and a number of books.

BELFAST.

Report of the Medical Officer of Health.—The report on the health of the County Borough of Belfast for 1906, just published, is of special interest, as it is the first report issued by Dr. Bailie, over whose appointment last year there was so much excitement. It is only fair to him to bear in mind that he was in office for just two and a half months of that year, and that many details which he might wish to include in the report were not to be obtained. But in spite of this, the report shows a very marked improvement on all previous ones, which year after year have been commented upon in these columns. It is a well printed and bound volume of nearly 200 pages, with four maps and eight charts and a good index. It is, indeed, pretty clear that Dr. Bailie has read and taken to heart the comments on the former reports. The report opens with a summary of the vital statistics for the year 1906, showing a population of 366,000, a birth-rate of 31, a death-rate of 20, a zymotic death-rate of 2.5, a phthisis death-rate of 2.7, and an infantile mortality of 143 per 1,000 births. There are two clear charts giving the total deaths at various age periods, and the principal causes of death. An interesting article on the population of the city shows that according to the Registrar-General's figures it was last year 366,000, but according to other calculations it was as much as 394,000. Calculated from the number of houses inhabited it was 388,000. The first four tables deal with zymotic disease and notifications, then several tables are devoted to phthisis. A study of the birth-rate shows that while it has fallen the fall is only trifling compared with many other cities. It was 31 per 1,000, as compared with an average of 31.7 for the previous ten years. The rainfall in Belfast is put at about 36 inches, but this hardly does justice to the city, for it is taken at the Antrim Road Water Works, where the fall is increased by the proximity of the hills. If taken in the centre of the city, or on the south or east side, it would probably be decidedly less. Table No. 11 gives the names of the dispensary medical officers, the population of their districts, and the number of cases of phthisis, whooping-cough, and measles voluntarily notified by each during the year. Generally speaking, the number of cases seems to be about inversely proportionate to the age of the medical officer! Typhoid has an article of 29 pages in length devoted to it, giving a history of a recent outbreak, and its connection with the milk supply—a very instructive report already given in some detail in this column a year ago. Table 15 shows that only nine cases of typhus were notified, with three deaths, a great improvement on many former years. Scarlet fever was prevalent, but the mortality was only 2.17 per cent. Diphtheria also was prevalent, and showed a mortality of 17.6 per cent. Two pages are given to disinfection, and details of the method and cost are given. Attention is being paid to books belonging to the Public Library in houses where infectious diseases had occurred. The subject of infant mortality is not as fully discussed as one could wish, and it is to be hoped that Dr. Bailie will devote much more than three pages to it in his next report. The rate in Belfast was 143 deaths under one year old, per 1,000 births, and a table is given showing the rate in a number of large towns, all of which, except Glasgow, are worse than Belfast. But we are not informed why these particular towns were selected, and we notice that London, Bristol, and Nottingham, for instance, are not included in the list. About twelve pages are given to the important subject of phthisis, and the views expressed are on the whole satisfactory. They show to a marked extent the influence of the late Belfast Health Commission, but are none the worse for that. The card of instructions for consumptives, which is distributed freely in the city, is re-published at length, and brief particulars are given of the work done by the various hospitals in combating the disease. There are five female inspectors engaged as health visitors in the city, and of the 13,000 visits paid by them last year 1,300 were to cases of phthisis. After a short notice of the water supply, seven pages are devoted to a consideration of the milk supply and questions connected with it. The gist of the article is that far wider powers are needed by the authorities if they are to deal satisfactorily with the difficult problem of infected milk. For several years past we have been asking for particulars as to prosecutions for adulteration of foods, etc., and now at last we get them. We find that 1,563 samples of foods and drinks were taken for analysis, and 67 were found to be adulterated. There were 61 prosecutions and 51 convictions, the fines amounting to £85. It is a pity we cannot have another table giving an estimate of the profits of undetected adulteration! The seizures of unsound food are also given, chiefly shellfish and fruit. Another table gives the number of pigs kept in the different districts of the city, and it is rather startling to find that the total is 2,770. The summary of the proceedings taken for the abatement of nuisances and the work done is most interesting, as is also the account of the public abattoir, in which 58,000 animals were killed and 179 seized as unsound. Ten pages are given to the work of Professor Symmers at Queen's College in examining specimens bacteriologically, a work the great interest of which merits separate notice, as it includes a careful examination into the bacteriology of the shellfish of Belfast Lough. The report ends with a good index and maps showing the localities in which the principal zymotic diseases occurred. As we said at the beginning, the report is a marked advance on its predecessors, and includes almost every point to the omission of which attention was called in former years. One thing is still omitted, and that is an account of the working of the refuse destructor. No doubt this is a concession to the feelings of some of Dr. Bailie's former colleagues on the City Council, who were responsible for the erection of this costly failure.

LETTERS TO THE EDITOR.

MEDICAL LAW AND QUACKERY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My letter of last week, in which I called attention to the weakness of medical laws as compared with the Veterinary Act, has drawn forth an interesting private communication from a distinguished F.R.S. professor of biology at a British University, from which I am permitted to publish the appended excerpts. If the profession propose to fight the battle of medical law reform with the necessary determination, it may be desirable sooner or later to discuss the question of getting proper representation in Parliament. One or two men with the power and will to make their voices heard might accomplish much; and if the sacrifice of time and income were too great to be conceded gratuitously, it would pay the profession to provide adequate incomes to members willing to devote themselves to political life. My friend writes:—"There can be no doubt that, both in the House of Lords and House of Commons, there are many men so ignorant of the whole field of biological science that they cannot understand the aim or necessity of the education that the qualified man has to pass through. I believe the root of the difficulty lies in the system of education in our higher public secondary schools, in which science is still stigmatised as 'stinks,' and which turn out as 'educated' men boys to whom the whole range of science is as a closed book. These men go into Parliament and public life not only ignorant of science but with an unveiled contempt for us. To their stupid brains the medical man is a kind of 'stinks' man, and ought to be treated with contempt. It is a pity that the medical graduates of some great University cannot unite to run a candidate for their seat irrespective of party politics, with a mandate to look after medical legislation. The doctors who do get into Parliament are mostly so bound by party ties that they cannot do much to promote medical Bills."

I am, Sir, yours truly,
HENRY SEWILL.

October 12th, 1907.

P.S.—Since writing the above, I have seen in the *Times* of to-day the full summary of Mr. Beale, the Australian Royal Commissioner's report, to which you refer in your editorial notes. If a single lay Commissioner with scanty powers can produce a solid indictment of quackery such as Mr. Beale has constructed, what might not be achieved by a Royal Commission armed with full powers, including the power to compel the attendance of witnesses and examine them on oath? In the papers of to-day appears also the news that in Germany there comes into action this month a law which, if administered with only a part of the zeal always displayed in matters affecting the welfare of the people of the Fatherland, will put an end at once to the traffic in fraudulent quack medicines and apparatus, and to the illicit practice to which that traffic serves everywhere as a cloak. What has been done in Australia and Germany can be done in these islands, and it will be done so soon as the profession unites to carry the matter through with unflinching courage and determination. H. S.

CONGENITAL ANOMALIES OF THE EYE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. J. Herbert Parsons must allow me to thank him for his courteous correction. What he said in his recent and admirable work on "Diseases of the Eye" was clear enough. But, unfortunately, some imp of mischief not wholly unconnected with the printer's office changed the "neuritis," as I originally passed the word, into the "pseudo-neuritis," as actually printed in the columns of THE MEDICAL PRESS AND CIRCULAR. I am glad to find that so competent an authority as Mr. Parsons is in accord with me in thinking that probably the optic disc is never abnormally swollen in pseudo-neuritis. Although it often appears to be so, I have never satisfied myself that such is actually the case.

I am, Sir, yours truly,
SYDNEY STEPHENSON.

33 Welbeck Street, W., October 13th, 1907.

AN APOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I write to you to say that, through no fault of mine, a sensational account of a lecture by me has appeared in the general Press. I see to-day extracts from it put together as if it had been an interview.

I cannot describe how profoundly sorry I am that this discreditable sensation has occurred, and wish to tender my humblest apologies through your medium to all members of my profession. I may hold singular individual views, but I have no desire to ventilate medical matters through the lay Press.

I am, Sir, yours truly,
BERNARD HOLLANDER.

35A Welbeck Street, Cavendish Square, W.,
October 10th, 1907.

[Of course, we publish Dr. Hollander's disclaimer, but we think it should be possible to prevent the publicity which his lectures obtain. As in at least one lay paper a photograph of Dr. Hollander appeared, it would seem that his friends are particularly apt to compromise him in the eyes of his colleagues.—ED.]

The following letter, addressed to the *Irish Independent*, may be of interest to our Irish readers:—

SIX BROTHERS DOCTORS.

SIR,—It would appear from your issue of yesterday that the Earl of Kilmorey, when distributing the prizes at the opening of the medical school at Charing Cross Hospital, felt surprised at learning that there are at present five brothers doctors. I daresay his lordship will be more surprised to hear that the late Dr. Macnamara had the pleasure of living to see six of his sons doctors, all making their mark:—Dr. G. M. Macnamara, who represents his father; Colonel John Macnamara, I.M.C.; Colonel William Macnamara, I.M.C.; Major M. Macnamara, I.M.C.; Major Robert Macnamara, I.M.C., who was appointed lately Inspector of Prisons out in India, and though last, not least, Dr. Joseph Macnamara, who has a very extensive practice in London. They are a credit to their name and country.

JOHN KERIN.

Corofin, County Clare, Oct. 3rd, 1907.

THE twentieth Congress of the French Surgical Association was opened in the great amphitheatre of the Faculty of Medicine in Paris on the 7th inst. The question for discussion was the influence of Röntgen rays on malignant tumours. Many well-known surgeons were present and took part in the discussion.

OBITUARY.

E. A. WRIGHT, M.D.EDIN., of Huddersfield.

WE regret to announce the death of Dr. Edward Arthur Wright, formerly of Huddersfield, which took place last week at Clevedon, Somerset. He had suffered from a painful malady, for which he underwent an operation about a week before. The deceased, who was 58 years of age, was the son of a Cheltenham clergyman. Entering upon a medical career, he became M.B. and C.M. of Edinburgh. In 1875 he was appointed assistant house surgeon at Huddersfield Infirmary. After holding that position for about two years, he commenced practice for himself, and in 1892 he was appointed one of the honorary surgeons at the Infirmary, and continued in that position until April 10th, 1905, when he resigned in consequence of ill-health, arising partly from injury received in a trap accident, but mainly from successive attacks of influenza. In consideration of those services, on July 28th, 1905, he was appointed honorary consulting surgeon to the Infirmary.

GEORGE FREDERICK ELLIOTT, B.A., M.D., F.R.C.P.

MUCH regret will be felt at the death of Dr. George Frederick Elliott, one of the highest esteemed members of the medical profession in Hull. The deceased gentleman, who had attained the ripe age of 73 years, died on the 6th inst. The late Dr. Elliott was the second son of Mr. William Elliott, of Strabane, County Tyrone, who was a member of the younger branch of the Elliotts of Cavan. An ancestral head of this family, Sir John Elliott, settled in Cavan, and was created a baron at the time of the Ulster rebellion in 1604. The deceased held the degrees of M.D. (Dublin), F.R.C.P. (England), and B.A. (Oxford). Upon qualifying as a physician he entered the Royal Navy, being attached to the medical staff of the first branch of the Imperial forces for eight years. Subsequently deceased held appointments at the Haslar Hospital and at the Melville Marine Hospital, Chatham. About forty years ago he came to Hull, where he rapidly acquired a practice of no ordinary proportions, for it extended into Lincolnshire. He was appointed physician to the Hull General Infirmary, as it was then called, in 1867, and, at the same time, lecturer on medicine at the Hull Medical School. When the present Convalescent Home at Withernsea was opened by Sir James Reckitt, Bart., he was appointed consulting physician. The late Dr. Elliott took no part in public life, being of a very retiring disposition. Deceased leaves a wife, one daughter, and four sons.

HENRY STOLTERFOTH, M.A. CAMB., M.D. EDIN.

WE regret to record the death of Dr. Henry Stolterfoth, which took place at Grey Friars, Chester, on October 4th, after a protracted illness. The deceased gentleman was a victim of that insidious disease, cancer, and had been constantly attended by Dr. Taylor. By his death Chester has lost one of its most useful and genial public men. Dr. Stolterfoth was educated at the King's School, Cambridge, and entered Gonville and Caius College, Cambridge, in 1856. He took honours (sen. opt.) in mathematics in 1859, and gained his M.A. degree in 1863. In 1868 he graduated M.D. at Edinburgh, and was awarded a bronze medal for chemistry. He then settled in practice at Chester, and took great interest in public affairs. In November, 1892, he was unanimously elected Sheriff, and six years later was installed in the mayoral chair in recognition of his public services. During his year of office the question of the amalgamation of Hoole with Chester engaged the attention of the City Council, and the Isolation Hospital at Sealand was opened. As a medical man and member of the Public Health Committee, Dr. Stolterfoth took a keen interest in the consummation of the latter scheme. He was connected with the Infectious Hospital at the Infirmary ever since its erection—a hospital which, he once said, had been of incomparable use to the city. In 1891 Dr. Stolterfoth was elevated to the magisterial bench, and in 1900 his colleagues on the Town Council conferred upon him the rank of Alderman. The deceased gentleman was one of the first to come in contact with the Rev. Charles Kingsley in connection with the formation of the Chester Society of Natural Science in 1871. He was a Liberal in politics and regularly appeared on the party platform, but there was no element of party bitterness in his nature, and he was highly respected both by political friends and opponents alike. He was seventy-one years of age, and leaves a widow but no family.

SPECIAL ARTICLES.

THE TUBERCULOSIS EXHIBITION IN DUBLIN.

The Tuberculosis Exhibition, which has been organised in Dublin by the Women's National Health Association, under the presidency of Her Excellency the Countess of Aberdeen, was opened last Saturday by His Excellency the Lord Lieutenant of Ireland, among the others taking part in the ceremony being the Chief Secretary (Mr. Birrell, M.P.) and Professor Osler. In declaring the Exhibition open, His Excellency read the following telegram from His Majesty the King:—"I am commanded by the King to express his good wishes for the success of the Tuberculosis Exhibition, the first of the kind ever held in Great Britain and Ireland, on the occasion of its being opened by you. His Majesty is greatly interested in the problem of checking the progress of this disease, and he trusts the Exhibition may be the means of directing attention of the public to the terrible ravages caused by this scourge and to the efforts that are now being made to arrest its progress."

Prior to the opening of the Exhibition the Consultative Committee had met in conference, and expressed warm approval of the arrangements made by the Executive Committee, while on the previous evening Professor Osler, M.D., had delivered an introductory lecture in the theatre of the Royal Dublin Society on the subject, "What the public can do in the fight against tuberculosis." Dr. Osler referred to the victories that had been won by sanitary service in the case of typhus, of malaria, and of typhoid fever, and held out hope for similar results in the case of tubercle. He said that the ground was prepared for tubercle by three bad habits, bad food, bad air, bad drink. He urged as practical measures the reorganisation of the public health service, compulsory notification of the disease, better housing of the poor, the erection of cheap sanatoria, and care of cases at home by district nurses.

In the Exhibition the exhibits are divided into four sections, the first, which supplies statistics showing the rate of mortality resulting from tuberculosis in different countries, being in charge of the Registrar-General. Diagrams are exhibited in this section illustrating the position which Ireland occupies among different countries with respect to the disease. Some of these diagrams show that, as compared with England and Scotland, Ireland's position is most unsatisfactory and discouraging. Thus, it is shown that whereas the death-rate from tubercle has diminished by nearly a half in England and Scotland during the past forty years, in Ireland it has shown a slight increase. Moreover, in Ireland the age incidence shows that the disease is most fatal in early adult life, the most productive period from an industrial point of view. The deaths from tuberculosis in Ireland in 1906 amounted to 11,756, a figure much in excess of the gross number of cases of mortality resulting from any other disease in that year. Of every hundred deaths from tubercle seventy-six were caused by phthisis. Statistics show that Ireland holds fourth place with regard to this disease among the British possessions and foreign countries. Maps specially coloured to throw into relief the parts of Ireland where tuberculosis is most prevalent show that the cities and urban districts are the most affected. No less interesting is the second section, devoted to pathology, human and veterinary. The exhibits in the first branch have been collected by Professor M‘Weeney, the greatest pathological or bacteriological expert in Ireland; and in the Veterinary Branch the exhibits are provided by the Royal College of Veterinary Surgeons of Ireland. In this are shown models prepared by Dr. Bermingham, of Westport, illustrating tubercle bacilli in the human sputum, when stained with aniline dyes and strongly magnified. These models are extremely beautiful for demonstration purposes, and will naturally attract much attention. They are an excellent representation of the appearance of the field of a microscope when examining a well-stained specimen of tubercular sputum. In this section are also shown slices of tubercular organs, both human and bovine, together with cultures of the tubercle bacillus.

The Appliances Section consists of a display of spitting cups, handkerchiefs, etc. A novel feature is the display of turf sods, hollowed out to act as spittoons, which can be burned after use. The idea is an excellent one.

Outside there are sleeping bungalows (models), or châlets, designed by Messrs. Kennan and Sons, and also by the contractors for the building of the Exhibition. There is also a sanatorium in the grounds. In the village hospital there is a screen, designed by Messrs. Smith and Sheppard, Dublin, to protect the body of a consumptive patient when the head is below the open window and to receive the pure air. The screen is quite an ingenious thing, for, while it provides that the body of the patient may be kept quite warm, the head and face may be exposed to the sun and air.

The Literary Section, under the control of Dr. Alfred Boyd, is of the utmost importance, particularly to members of public health authorities, and to medical officers of health, since it shows what has been done by municipal authorities elsewhere in the campaign against tuberculosis. Most notable is the exhibit from the borough of Northampton, where, under the executive control of Dr. James Beatty, the death rate from phthisis has been reduced to the extraordinarily low figure of 0.87 per 1,000. There are also tables which deal with the question of infection, segregation, and treatment of consumption, while the relations existing between overcrowding and mortality in the London district are shown by a series of diagrams constructed by Sir Shirley Murphy, Medical Officer of Health to the London County Council. Large diagrams, procured by the Public Health Department of Birmingham, show the industrial occupations in the death-rate from consumption. In that city, and in Sheffield, the system of compulsory notification—it is voluntary everywhere else, these cities having got special Parliamentary powers to enforce compulsory notification—is dealt with. In Manchester the system of milk inspection, as regards city dairies and milk arriving from the country, is shown by a selection of forms. There are also exhibits from Dublin, Belfast, Edinburgh, Bristol, Glasgow, Liverpool, Cardiff, Brighton, and New York. A number of popular pamphlets dealing with tuberculosis are shown, and an interesting feature to those caring for the history of the subject is the valuable collection of medical works lent by Dr. Kirkpatrick.

In the Domestic Section, arranged by Dr. Ella Ovenden and Dr. Lily Baker, are exhibits of milk sterilisers, etc., while demonstrations on invalid cookery are being given each day.

A series of popular lectures is also being given daily, among the lecturers this week being the Registrar-General, Dr. Bermingham, Mr. Lintargin, and Professor Lindsay.

The whole exhibition reflects credit on the Executive Committee, and particularly on the honorary secretaries, Mrs. Rushton and Dr. Alfred Boyd.

THE LONDON MEDICAL EXHIBITION.

The third of the series of Medical Exhibitions, organised by the *British and Colonial Druggist*, has achieved a no less signal success than that of its predecessors. From the day of its opening, on October 7th, to the last hour of its existence, on October the 11th, it was a centre of attraction for a constant succession of medical practitioners. The excellence of the general organisation was well supported by the variety and novelty of the numerous exhibits, which included drugs, foods, instruments, invalid furniture, and a heterogeneous collection of things interesting to those engaged in medical practice. In the present notice it will be possible to mention only a few of the most important exhibits. So far as genuine novelty is concerned the first place may perhaps be allotted to novocain, introduced by the Saccharin Corporation. It need hardly be remarked that the special interest attached to this drug is due to its superiority over cocaine as a non-irritant and non-toxic local anæsthetic. The most important application, however, is in the production of spinal analgesia, which bids fair to revolutionise the field of general anæsthesia for surgical purposes. The adjoining stall of Meister Lucius and Bruening contained a number of interesting synthetical and other products, such as lumenol-ammonium (an antiseptic), holocain, orthoform (local anæsthetic), and various tuberculins. Messrs. Brand, as befits a firm of their reputation, had a stand excellently equipped with invalid soups, jellies, peptonised foods, and other preparations of the kind. The International Plasmon Company showed a series of their well-known products. Cadbury Bros. were well represented, and the Angier Chemical Company were well in evidence with their famous emulsion, to which they have added a throat tablet. Mr. George Back held a popular stall, in which he exhibited samples of his famous diabetes whisky. A prominent feature was Messrs. Baillière, Tindall and Cox's books, which occupied a commanding position in the hall; amongst other well-known volumes we noticed Stewart's "Physiology," Jellett's "Midwifery," Macnaughton-Jones' "Diseases of Women," Rose and Carless' "Surgery," and Walsh's Röntgen Rays." The Equipoise Company showed their most ingenious and handy couches and beds, which are so contrived as to adapt themselves automatically to the movements of a patient's body; they have only to be seen to be appreciated. Messrs. Fairchild and Co. had a striking exhibit of their famous digestive products, including the original trypsin preparations, about which so much has been heard in the treatment of cancer. Messrs. Knoll and Co. showed samples of their fine chemicals, notably styptol (for uterine hæmorrhage), santyl (a non-irritating santal preparation), and the well-known diuretin. Messrs. Armour and Co. had an elegantly arranged stall; their pepsin and other digestive products were shown, together with various suprarenalin, red marrow, cerebrin, and other organic drug products, including notably one of thyroid elixir. Messrs. Christy and Co. had a large and well-filled stall: amongst its many attractions was the novelty "Anasarcin," which is claimed to have an excelling virtue in cases of dropsy: this firm also shows a convenient and cheap electric lamp fitted with mirrors for throat work. Their glyco-thymoline is too well-known to need more than passing mention.

Messrs. Ingram and Royle showed specimens of the numerous spa and other waters of which they are proprietors or agents. Possibly one of the best stalls in the Exhibition was that of Parke, Davis and Co., which it would be hard to beat for the variety, novelty, and excellence of its exhibits. Space does not permit us to do more than mention the typhoid agglutinometer, a cheap and handy method of performing the Widal test without a microscope. Their germicide soap is excellent, and their digitalone, formidine, iodalbin and petroleum emulsion are deserving of close attention.

Jeyes' Sanitary Compounds Company had all their excellent preparations of cyllin, one of the best modern disinfectants and germicides, well arranged on a handsome stall. Zimmermann showed such specialties as urotropin, Beta eucain, argentamine, iodol, and orexin. Messrs. Merck had a number of valuable pharmaceutical preparations, including iodopin, dionin, styptican, and veronal. Messrs. Nestlé and Co. showed their Milo food, which is modified by the omission of starch from their former preparation. They also have a most excellent product issued under the name of "Ideal milk in bottles." Messrs. Peek, Frean and Co. exhibited their new and admirable Tillia biscuits. Messrs. Allen and Hanbury had a peculiarly attractive display of instruments and appliances, amongst which may be noted the pocket urine testing cases, and a good syringe for novocain. The Miol Company exhibited their particular product, which is a good combination of cod-liver oil and malt; Bovril lozenges, essences, and invalid Bovril were well represented, as well as their hardly less important preparation Virol. Wright's Coal Tar Soap, a household word in medicine, was well displayed. Messrs. Martindale had a very large collection of drugs, preparations, appliances, and instruments, many of them of a novel and interesting kind. Their list was headed by their world-famed "Extra Pharmacopœia." Friedrichshall water was of course on show, as one of the oldest and most popular of its class. The Charles H. Phillips Co. showed their well-known milk of magnesia and phospho-muriate of quinine compound. Antiphlogistine was well to the front in the stall of its enterprising proprietors, the Denver Chemical Co. Lastly, Defries and Sons showed the Pasteur and other modern filters, as well as some good disinfectors. On the whole the Exhibition may be regarded as a convenient means of acquiring a good deal of liberal education in many practical medical matters.

REVIEWS OF BOOKS.

DERMATOLOGY. (*a*)

This volume includes some thousand pages of crown octavo size, illustrated by numerous excellent photographic reproductions. It forms one of the most serious American contributions to dermatology that we have seen for some years. On every page it bears the stamp of scholarly handling and of wide information and practical knowledge. The anatomy and physiology of the skin, and the principles of its general etiology, pathology, symptomatology, and treatment are somewhat fully dealt with. In speaking of the drug rashes the author remarks that:—"If these various rashes can be produced by drugs, it is not difficult to conceive of analogous eruptions resulting from other toxic substances." That view was advanced by Walsh in this country at least fifteen years ago under the name of "Excretory Irritation." Dr. Pusey has also advanced that writer's illustration of the finding of bromine and iodine in corresponding rashes and other views. The account of urticaria is adequate, yet concise, and the author justly states that diagnosis of the condition is the smallest part of the problem, the chief difficulty being the determination of the causative factor. In the discussion of alopecia areata and universalis, curiously enough we find no allusion to the relation of that condition with myxœdema and Graves' disease. In the brief space at command, however, it is clearly impossible to take more than a general survey of so great a mass of carefully collated and edited matter. We may therefore say that in our opinion this book will be found of value to all who wish special information in diseases of the skin. It is written in a clear and pleasing style, and is thoroughly well edited. A last reference may be made to the 368 illustrations, which are among the best of the kind we remember to have seen in any work upon dermatology

DISEASES OF THE LARYNX. (*b*)

This short work is worthy of commendation, as it is one which can be placed in the hands of senior students and members of post-graduate classes. The arrangement is excellent and the drawings are good, and as the author in the preface says, "the intention has been to picture the more typical appearances as an aid to their recognition and diagnosis." The illustrations of instruments are useful, as those in everyday use are portrayed, not as is so often the case those of a byegone generation. A short but good account of the newer methods of examination such as "Bronchoscopy" is introduced, and the description of the commoner operations are lucid.

(*a*) "The Principles and Practice of Dermatology." By Wm. Allen Pusey, A.M., M.D., Professor of Dermatology in the University of Illinois, etc. London: Sydney Appleton. 1907. 25s. net.

(*b*) "Diseases of the Larynx." By Harold Barwell, M.B., F.R.C.S. London: Henry Frowde and Hodder and Stoughton.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Post-Operative Results of Prostatectomy.—F. Cabot gives a series of 62 cases, with four deaths (*Postgraduate*, September, 1907), from his experience of the operation of prostatectomy. He advises: 1. Never remove a prostate if there is any question of the patient's fitness to resist the shock; do a preliminary drainage, suprapubic, and await developments. 2. Employ local anæsthesia for the preliminary cystotomy when possible. 3. Never use ether for prostatic enucleation. 4. Be sure the bladder is completely drained after the operation, and that the patient leaves his bed in a day or two for his meals. 5. Choice of method: perineal route in 20 per cent.; suprapubic at one sitting 40 per cent.; Lilienthal's interval operation, 40 per cent. 6. Perineal route suitable for simple uncomplicated prostatic hypertrophy (when small). 7. Suprapubic route in all severe, complicated cases, and in about one-half of these cases the two stage methods of Lilienthal should be employed. 8. Cystoscopy is of value, but prolonged efforts to use it should not be employed. G.

Congenital Stenosis of the Pylorus.—H. Sheffield (*Postgraduate*, August, 1907).—Stenosis of the pyloric end of the stomach may be complete or partial. In the first case death is only a matter of hours; in the second, the child may live, and, if suitably treated, recover. While complete atresia is very rare, and almost never diagnosed until a post-mortem examination reveals the condition, a partial stenosis is by no means uncommon. The true stenosis is invariably due to a congenital narrowing of the lumen of the pylorus, and is associated with more or less hypertrophy of the pyloric ring. False or spastic pyloric stenosis is the result of congenital faulty inervation of the stomach, or of acquired digestive and nervous disturbance. It is free from primary hypertrophy of the pyloric ring. Sooner or later secondary hypertrophy of the muscular and mucous coats of the stomach occurs in consequence of the increased force required by the stomach to expel its contents. The symptoms, as a rule, are definite. After a period of from one to three weeks' good health, the infant begins to vomit; this vomiting increases in severity; the amount of food brought back often appears greater than the child had swallowed, and is free from bile. There is pseudo-constipation, with scanty concentrated urine. The child appears to be nearly always hungry, but after a few mouthfuls of food is seized with colicky pains and refuses its bottle, only to grasp it again when some relief prevails. The abdomen is sunken in below, while the epigastrium is distended. In some cases the hypertrophied pylorus may be palpated as a distinct tumour. In the cases of false or spastic stenosis, the symptoms are much the same, but are not so marked. This form of disease may, and often does, yield to medical treatment, the true stenosis, on the other hand, being always fatal unless treated surgically. The author believes, in all cases of congenital pyloric stenosis, if after two weeks' faithful but unsuccessful trial of dietetic and medicinal treatment, an operation should be recommended in bottle-fed children presenting the usual symptoms of pyloric stenosis, plus pyloric tumour. In breast-fed infants presenting the usual symptoms of pyloric stenosis, even if there be no palpable pyloric tumour present, the choice between divulsion, pyloroplasty, and gastro-enterostomy depends upon the pathological condition of each individual case. G.

Primary Cancer of the Appendix.—Hartmann (*Bulletin de Chir.*, No. 8, 1907) reports two cases of carcinoma of the appendix, occurring in a series of 50 cases examined for carcinoma, and mentions 40 other cases of this disease which have been recorded during the past three years. It seems most probable that carcinoma is a far more common affection of the appendix than is generally supposed. The growth is usually very small, and readily escapes notice in the inflamed appendix unless most careful microscopic search is made. The cancerous growth in most cases involved an obliterated part of the appendix. In most of the cases the growth has been an adeno-carcinoma, and developed mainly between the ages of twenty and thirty years. The prognosis of the disease is uncertain, but cases are recorded in which no return of the disease had taken place four years after the removal of the cancerous appendix. G.

Important Change in the Blood and Urine in Appendicitis.—A. Pisani (*Postgraduate*, September, 1907) gives a number of cases of appendicitis in which a careful examination of the blood and urine had been carried out. From these he draws the following conclusions: The necessity for cleansing the intestinal canal by cathartics, thereby eliminating all causes which tend to produce any toxins due to putrefactive fermentation of the food-stuffs. (2) Abstaining from administering opiates or narcotics to relieve the pain, which mask the symptoms and cause constipation. (3) The obtaining of a thorough and accurate blood count, so as to arrive at a diagnosis whether pus formation exists, or especially obtaining a radionuclear count of the leucocytes so as to be able to form some opinion as to prognosis. (4) Frequent urine analyses, testing especially for indican, which would tend to show that putrefactive processes exist in the human economy, and that the disappearance of the same after operation proves progress of the patient. (5) The total daily output of urea should be determined daily in all inflammatory and suppurative processes, to see whether resolution is taking place, and the rapidity of the resolution, and when and how rapidly the repair is being effected. G.

A New Operation for Mobile Kidney.—Stanmore Bishop (*Brit. Med. Journ.*, October 5th, 1907) reaches the kidney through the anterior abdominal wall. The peritoneum is divided transversely over its lower pole, and the true capsule of the kidney is also split across just below the renal pelvis. The capsule is then stripped inwards and downwards from the kidney, still, however, remaining attached internally and posteriorly. The divided edges of the peritoneum are re-united. A long silk thread, armed at each end by a long straight needle, is then taken. One of these needles is inserted in an antero-posterior direction immediately below the lower edge of the renal pelvis, passing through the peritoneum, reflected capsules, and muscles of the back, and emerging through the skin behind. The second needle is in like manner passed at the inner border of the kidney 1 to 1½ cm. lower down. Three or four similar stitches are passed around and below the kidney in the same way. Each pair of threads forming a loop is then drawn up firmly and tied in a groove formed by the division of the skin between them, so becoming buried. The tying of the loops draws the incisions between the needles into a point, so that no suturing of the skin is required. The abdomen is then closed. The author has performed this operation in 10 cases. The first two relapsed, as a grip of the kidney capsule was not taken by the stitches. S.

Fracture of the Neck of the Femur: A New Treatment.—Gallie (*Canada Lancet*, September, 1907) says that the clinical efficiency of the method of treatment detailed below has been corroborated by observations made on eight cadavers. The procedure is as follows: The patient is anæsthetised and elevated on a pelvic rest, which does not interfere with the bandages as they are applied. The surgeon stands beside the injured hip. If the fracture is impacted, an assistant forcibly abducts the limb under moderate traction, breaking down the impaction and only stopping when an angle of 50 degrees from the normal has been reached. The surgeon maintains a downward pressure on the trochanter with the palm of the hand, and gently lifts it forward, and rotates the limb slightly inwards. No attempt is made to elicit crepitus. If the fracture be complete and unimpacted, the assistant first overcomes all shortening by strong traction, counter traction being provided by a towel against the perineum. He then abducts the limb in the same way. When the surgeon is satisfied with the results of the manipulations, the bony points are padded, a plaster spica is applied from the toes to the mammary line. The plaster is well moulded in by the side of the pelvis and trochanter, so that displacement may be rendered impossible. After some days an X-ray photograph should be taken through the plaster. The best time for the application of the treatment is immediately after the injury, unless lacerated tissues require preliminary treatment. At the end of four weeks the plaster case may be shortened to allow free movement of the knee, and may be completely removed in eight weeks. After this the best routine plan is to use a light short plaster spica, holding the limb in moderate abduction. At first the patient uses crutches, and then gradually resumes weight-bearing. This plan of treatment is recommended for all fractures of the neck of the femur occurring in the young and in adults up to 55 years of age. S.

The Treatment of Weak or Flat Foot.—Whitman (*Med. Record*, August 31st, 1907) says that the influence of modified shoes (raised on the inner side), attention to posture, and the cultivation of muscular strength may be quite sufficient to cure milder cases of the above disability, if the co-operation of an intelligent patient is assured. Exercises are most important. As the adductors of the foot have been weakened by inactivity, the patient is instructed to invert the foot voluntarily over and over again. The following exercise is most important: The patient stands erect, markedly toeing in, with the weight thrown on the outer borders of the feet. The body is then raised on tiptoe with the full extension of the limbs; then it is allowed to sink slowly back, the feet during the descent being gradually inverted, reaching finally the extreme limit when weight is borne. In most cases, however, the tendency towards deformity has advanced so far that it cannot be controlled by the patient, and a brace is usually an indispensable adjunct in treatment. Whitman's brace is made as follows: A plaster mould of the foot, slightly adducted, is first made. On the cast from this the brace is fitted. Its inner margin rises above the astragalo-navicular joint. The outer side covers the anterior two-thirds of the os calcis and the cuboid bones, enclosing this joint. The sole part of the brace extends from the bearing surface of the heel to the bearing surface of the first metatarsal bone. The front and outer two-thirds of the sole are not supported unless there is breaking down of the metatarsal arch. The author considers that a brace should not be an agent to supplant developmental treatment, but one that, by enforcing normal posture, makes such treatment effective. S.

Skin Grafting by a Modification of the Wolfe-Krause (Whole Thickness of the Skin) Method.—Young (*Glasgow Med. Journ.*, October, 1907) describes eleven cases demonstrating the excellent results obtained in his modification of the above method of skin grafting. The grafts are made expeditiously by cutting straight down to the aponeurotic covering of the muscles. The whole flap is removed and placed in warm saline. The fresh wound is forthwith closed completely by suture and dressed with aseptic care. The surface to be grafted is now uncovered. If it is a fresh operation wound, the only preliminary to the application of the graft or grafts is the thorough checking of hæmorrhage. If asepsis of the wounds is not practicable, as in burns, all necrotic tissue and exuberant granulation should be removed some days before, and the surface of the ulcer should be smooth and of a healthy rose-pink colour. Contrary to the teaching of Thiersch, it is unnecessary, and probably a disadvantage, to remove the superficial layers of a granulating surface. The flap of skin and fat is now placed on the palm of the hand, and the fat is readily and quickly removed by cutting it away with a scissors curved on the flat. If the surface to be covered is large, the flap is divided into a number of pieces. The wound, when the grafts have been applied, should be covered with oil-silk or gutta-percha tissue suitably perforated. This protection is not interfered with for several days. The moist saline dressing outside the protection should be changed daily. The author calls special attention to the case of a woman, æt. 70, in whom, although she was in a practically moribund condition, the grafts lived and grew peripherally. Microscopic section of the grafts (obtained post-mortem eight days later) strikingly demonstrated the greater activity in initial extension of the stratum lucidum as compared with the rest of the superficial layers of the skin. S.

The Production of a Filtering Cicatrix in Chronic Glaucoma.—Félix Lagrange (*The Ophthalmoscope*, September, 1907) has devised the following operation for producing a filtering cicatrix without producing an entanglement of the iris. Eserine is instilled half an hour before operation to facilitate the passage of the knife, and to keep the iris away from the wound. After cocaine and adrenalin have been well instilled, the sclera is punctured 1 m.m. from the limbus, and the counter puncture is made at a corresponding point. The sclera is divided in the irido-corneal angle. In finishing the incision, the cutting edge of the blade is directed backwards, so that the sclera is bevelled "like the mouthpiece of a flute," and a large conjunctival flap formed. Without injuring the conjunctival flap, a piece of the exterior lip of the incision is resected with very sharp, specially made curved scissors. The iridectomy is now performed in the ordinary way, and the conjunctival flap used to cover the wound. Lagrange has published 27 cases treated by this operation, which have been watched for periods exceeding six months. Of these, four were not followed, and three remained without result, because he failed to obtain a filtering cicatrix on account of excising too small a piece of the sclera. The remaining 20 cases were good results—the vision having been improved in twelve and maintained in eight. M.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.

At a quarterly meeting of the Council, held on Thursday last, Mr. Henry Morris, president, was elected to give evidence on behalf of the College before the Committee which has been appointed by the Home Secretary on the subject of the "London Ambulance Service." Mr. H. H. Clutton was elected a member of the Executive Committee of the "Imperial Cancer Research Fund," in place of Sir John Tweedy, retired, and Mr. Edmund Owen was re-elected a member of the same Committee. Mr. L. A. Dunn, surgeon to Guy's Hospital, was introduced, and, having made the required declaration, was admitted a member of the Court of Examiners.

The Secretary reported the death of Mr. Timothy Holmes, and the Council passed a vote of condolence to his widow, at the same time placing on record their appreciation of the services rendered by Mr. Holmes to the College in the conscientious discharge of the several duties which for many years had devolved upon him. The Council also expressed their deep regret at the death of Professor Charles Stewart, and their sincere sympathy with his widow and family in their bereavement. The Council further expressed their sense of the great advantages which the College had derived from Professor Stewart's rare knowledge of all branches of science represented in the Museum, and recorded their appreciation of the zeal and ability which he displayed in performing the duties of Conservator of the Museum during the past 23 years.

The following candidates were admitted Members of the College: R. Jamison, M.A., St. Bart.'s; R. J. P. McCulloch, Toronto and Lond. Hosp.; C. H. Montgomery, Toronto; D. G. Pearson, Cambridge and St. Bart.'s; and A. J. Turner, Durh. Univ. and London Hosp. The president reported that he attended the centenary celebrations of the Geological Society of London as the representative of the College, and had presented an address of congratulation on behalf of the Council. The report to be presented to the Fellows and Members at the annual meeting, which is to be held at the College on Thursday, November 21st, was considered and adopted.

Deaths under Anæsthesia.

A verdict of death by misadventure was returned on the 14th inst. by a coroner's jury in the case of a married woman, 29 years of age, who died at Guy's Hospital on October 3rd, whilst undergoing an operation (tying the inferior thyroid arteries) for exophthalmic goitre. Chloroform was administered by the house surgeon, and ten minutes after inhalation commenced the patient turned colour and died, directly after the surgeon, Mr. C. J. Symonds, had made his incision. The heart was somewhat dilated and fatty. Both the surgeon and the house surgeon admitted that the case was one of recognised anæsthetic danger. The Coroner of the City of London, Dr. Waldo, pointed out that, in spite of that fact, the chloroform was entrusted to the house surgeon, who had administered anæsthetics in 98 cases only, instead of to one of the eight anæsthetists attached to the hospital. The question raised was one of system. Whilst recognising the necessity of medical men being trained in the administration of anæsthetics, he maintained that all cases of known gravity should be entrusted only to anæsthetists of long experience. The jury found that the chloroform was administered with reasonable skill, considering the limited experience of the administrator. They appended a rider recommending that in future operative cases of a serious nature anæsthetics should be administered either by a staff administrator or under his immediate supervision. They also recommended that full statistical returns of all anæsthesia cases should be kept at Guy's Hospital.

Great Northern Central Hospital, London, N.

An attempt is being made at the hospital to utilise the exceptionally large amount of clinical material which is available for the purpose of teaching and study. A course of clinical lectures has been arranged, the second of which will be given on Friday, October 18th, by Mr. Arthur Edmunds on "Some Practical Points in the Diagnosis and Treatment of Appendicitis." In addition to this, the wards and out-patients' department are open to students and practitioners of medicine, and demonstrations are given at regular hours. The hospital contains 160 beds, a double set of operating theatres, and accessory rooms, and all the equipment of a first-grade modern hospital. The opening of two new electric railways with stations at Holloway Road and Highgate respectively has made the hospital one of the most accessible in London; and this fact, combined with the abundance of material for study, should make the hospital of much more than local importance.

A Medical Motorist.

At Ongar, on October 5th, Dr. Butler Harris was summoned for motoring at an excessive speed. The police evidence was to the effect that defendant drove his motor-car at 30 miles an hour. Defendant absolutely denied that he was going at 30 miles an hour, because his car was incapable of doing it. On the day in question he attended a patient at Coopersdale, and hearing that someone had been seriously injured at a farm fire at Stanford Rivers he hurried forward, but found that this was not so. He protested against medical men being pilloried in this manner. This was the fourth time within the last three years that he had been before the Justices for motor driving, and only on one occasion—when the case was dismissed—had there been any allegations of reckless or inconsiderate driving. If the police continued to pillory him in this way it would make the continuance of his country work almost an impossibility, because there was probably no day upon which he did not go at the rate of 23 or 24 miles an hour on some part of his journey. He objected to the method of timing adopted by the police. Drivers heard nothing of the matters until two or three days had elapsed, and were therefore unable to prepare a defence. The Chairman, Mr. Tyndale White, said there was nothing in the Act to exempt medical men, although, personally, he sympathised with them, and wouldn't mind them going 60 miles an hour—he would only be too pleased. The Bench much regretted having to fine defendant £3 and costs, 4s., but they had no alternative.

Supt. Laver said these motor traps were set in consequence of complaints, and the proceedings were taken by order of the Chief Constable.

City Medical Officer's Bereavements.

Mrs. Collingridge, the wife of Dr. Collingridge, of Penrith, was found in her room dead from prussic acid poisoning. Mrs. Collingridge had only been married three months, and lately had apeared strange in her manner. As she did not appear yesterday morning her bedroom door was burst open, and Mrs. Collingridge was found dead. A bottle that had contained prussic acid was by her side, death having taken place several hours earlier.

Dr. Collingridge, who is the son of the medical officer for the City of London, is at present in a fever hospital, and Mrs. Collingridge, senior, died suddenly at Morland only a fortnight ago. The lady who was found dead yesterday was a daughter of Professor Klein, of Twickenham, and had arranged to meet her husband on his discharge from hospital to-day, and travel south with him. When he went into the hospital, suffering from scarlet fever, she went to her home, but returned to Morland on Saturday. On Monday and Wednesday she visited her husband, and on Thursday evening she appeared to be in good spirits. At the inquest the jury found a verdict of "Suicide during temporary insanity."

Royal Academy of Medicine in Ireland.

At the annual stated meeting of the Royal Academy of Medicine, held on the 11th inst., the following officers and Councils were elected for the coming year:—President, J. Magee Finny; General Secretary, James Craig; Secretary for Foreign Correspondence, Sir J. W. Moore.

Medical Section.—President, The President, R.C.P. (Joseph M. Redmond); W. J. Dargan, H. C. Drury, T. P. C. Kirkpatrick, J. A. Matson, T. G. Moorhead, A. R. Parsons, G. Peacocke, F. C. Purser, W. J. Thompson, W. A. Winter.

Surgical Section.—President, The President, R.C.S. (Sir H. R. Swanzy); C. A. Ball, Alex. Blayney, Sir A. Chance, G. J. Johnston, R. C. B. Maunsell, Seton Pringle, J. B. Storey, E. H. Taylor, W. Taylor, W. I. de C. Wheeler.

Obstetrical Section.—President, E. H. Tweedy; J. S. Ashe, Paul Carton, Gibbon FitzGibbon, M. J. Gibson, H. Jellett, F. W. Kidd, R. D. Purefoy, J. Spencer Sheill, A. J. Smith, Sir W. J. Smyly.

Pathological Section.—President, A. R. Parsons; H. C. Earl, L. G. Gunn, W. G. Harvey, H. C. Mooney, T. G. Moorhead, J. F. O'Carroll, A. C. O'Sullivan, J. A. Scott, A. H. White, J. T. Wigham.

Section of Anatomy and Physiology.—President, A. F. Dixon, A. Fraser, H. M. Johnston, E. L'E. Ledwich, E. P. M'Loughlin, W. H. Thompson.

Section of State Medicine.—President, W. R. Dawson; A. E. Boyd, T. P. C. Kirkpatrick, F. C. Martley, J. A. Matson, G. S. R. Stritch, W. A. Winter.

Westminster Hospital.

Under the chairmanship of Mr. A. H. Tubby, M.S., F.R.C.S., a highly successful annual dinner of the Past and Present Students of the Westminster Hospital took place at the Trocadero Restaurant on Thursday, October 3rd. In proposing the toast of "The Westminster Hospital and Medical School," the chairman pointed out the satisfactory working of the arrangement made with King's College for the teaching of the preliminary subjects. In these days, when the diminution in the numbers of medical students in London compelled the larger hospitals to put forth every effort to attract men, it became increasingly difficult for the smaller schools to keep up their numbers.

The Dean, Mr. Paton, in his reply, urged upon all Westminster men the necessity for individual effort in support of the school. It was in the power of the old students, much more than in that of the staff, to secure new students. Dr. Allchin, in proposing the toast of "The Guests," said the presence amongst them of Professor Halliburton and Professor Thompson was eloquent of the happy relations now existing between Westminster and King's College. The health of the "Old Students" was proposed by Dr. Hebb, and acknowledged by Dr. Macnamara.

Meath Hospital, Dublin.

The opening meeting of the session at this hospital was held on Wednesday last, when Dr. James Craig delivered the inaugural address. The President of the Royal College of Physicians presided, and the meeting was addressed by, amongst others, the President of the Royal College of Surgeons, Dr. J. M. Finny, Sir John Moore, and the Provost of Trinity College. Dr. Craig, whose address we hope to publish in a later issue, dealt with "The Choice of a Medical Career and Medical Ethics."

The Treatment of Lunatics.

At the meeting of the Hampstead Board of Guardians on October 10th, a letter was read from the Commissioners in Lunacy saying that they had seen in "The Times" a report of the inquest on the body of a man who died in the observation ward of the Hampstead Workhouse after having been there 17 hours, seven of which were spent in a strait jacket, without being seen by a doctor. The Commissioners presumed that the guardians would hold an inquiry into the circumstances, and they would be glad to be informed of the decision at which the Guardians might arrive. A letter was also read from Mr. Walter Schröder, the deputy coroner, stating that at the inquest the jury added a rider to their verdict to the effect that they considered it very desirable that every patient should be seen by the medical officer upon admission, or as soon after as possible, and that in no case should a strait jacket be applied without the authority of the medical officer. Mr. Schröder added that he had also sent a copy of the rider to the Local Government Board. Mr. H. C. Russell, the master of the workhouse, said that after the inquest he instructed the lunatic attendants to notify the medical officer immediately of the admission of any patient to the observation ward. It was resolved to refer both communications to a committee of the whole board for consideration and report.

London County Council Scholarships.

The London County Council will be prepared to award, in January, 1908, not more than six scholarships to students in midwifery. Candidates must be between the ages of 24 and 40, and must be resident within the County of London. The value of each scholarship will be £25, and the course of training provided will extend over a period of six months. Forms of application may be obtained not later than Saturday, November 19th, from the Executive Officer, L.C.C. Education Offices, Victoria Embankment, W.C., from whom further information may also be obtained.

PASS LISTS.

University of Glasgow.

The following candidates have passed the second professional examination for the degrees of M.B. and Ch.B. in the subjects indicated (A., Anatomy; P., Physiology; M., Materia Medica and Therapeutics):—

Archibald Aitchison (M.); William Shanks Alexander, M.A. (A., P.); John Allan (A., P., M.); Andrew Clark Anderson (A.); James George Anderson (A. P.); William Anderson (A. P. M.); Edgar Barnes, M.A. (A.); Arthur Munby Bayne (A. P.); Emile Augustine Cameron Beard (P. M.); Douglas Morris Borland (M.); John Adam Gib Burton (A. P.); James Cairns (A., P., M.); John Allan Munro Cameron (A., P., M.); James Lang Cochrane (A., P., M.); David Rutherford Cramb (A.); Charles Duguid, M.A. (M.); Thomas Scoular Fleming (P. M.); George Fletcher, M.A. (A.); Edward George Glover (M.); Robert Dunlop Goldie (M.); Joseph Graham (M.); John Granger (M.); John Gray (P. M.); William Howat, M.A. (A., P., M.); William Howie (P.); James Walker Jones (A., P., M.); David Neilson Knox (M.); Alexander Leishman (A. P.); William M'Adam, M.A. (M.); William Charles Macartney (A.); Donald M'Dougall (M.); Donald M'Intyre (A.); Thomas Mackinlay (M.); Donald Mackinnon (M.); William Alexander Maclennan (P.); Campbell Macmillan (A., P., M.); John William M'Nee (M.); Thomas Marlin (M.); William Aubrey Layard Marriott (A.); Donald Meek (A. M.); Angus Millar (P.); Hyacinth Bernard Wenceslaus Morgan (M.); Findlay Murchie (A. P. M.); Frederick Lewis Napier (A.); William Nicol (A.); Clark Nicholson, M.A. (A., P.); John Robertson (A., P.); William Wilkie Scott (A.); William Alexander Sewell (M.); Alexander Hunter Sinclair (A.); James Stewart Somerville (A. M.); Richmond Steel (M.); Arthur Ford Stewart (M.); Robert Sweet (M.); Aidan Gordon Wemyss Thomson (M.); Charles Hermann Wagner (A., P., M.); William Samuel Waterhouse (M.); James Brown Whitfield (M.); Henry Joseph Windsor (A., P., M.); William Richard Wiseman, M.A., B.Sc. (A., M.); David Yellowlees (M.); Douglas Young (M.); John Young (M.). Women.—Christina Barrowman (A.); Florence Ann Gallagher (A.); Euphemia Adamson Hay (A., M.); Jeanie Douglas M'Whirter, M.A. (A., P.); Margaret Muir (A.); Ethelwyn Mary Walters (M.); Marion Aitken Wylie, M.A. (A., P.).

The following have passed the third professional examination for the degrees of M.B. and Ch.B. in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

David Anderson (M.); Thomas Archibald (M.); William Hunter Stirling Armstrong (P.); John Atkinson (P.); Alexander Ballantyne, M.A. (M.); John Blakely (M.); James Nimmo Brown, M.A. (M.); William Barrie Brownlie (M.); John Cameron (M.); Matthew Ignatius Thornton Cassidy (M.); Donald Clark (P.); Donald James Clark (M.); Alexander Beck Cluckie (M.); James Cook (Coalburn) (P. M.); Walter Dawson (P.); Thomas Scott Forrest (M.); William Leonard Forsyth (P.); John Fotheringham, B.Sc. (P., M.); Robert Dunlop Black Frew (P., M.); William Ernest Gemmell (M.); Alexander Thomas Arthur Gourlay (M.); Edward O'Driscoll Graham (P.); Thomas Harkin (P.); John Mitchell Henderson (M.); John M'Lean Hendry (P.); James Hall Hislop (P., M.); William Alexander Hislop (P. M.); Walter Hermann Kiep (P., M.); James Towers Kirkland (P.); William Leitch (P., M.); Daniel Conway M'Ardle (P.); Frank Crombie Macaulay (M.); Robert M'Carlie (P.); Joseph Glaister M'Cutcheon (P.); Alexander Macphail Macdonald (M.); William M'Kendrick (M.); Murdo Duncan Mackenzie (M.); Francis William Mackichan (M.); William Campbell Mackie (M.); John James Mackintosh (P., M.); James M'Millan M'Millan (P., M.); Allan Macpherson (M.); Murdo M'Kenzie M'Rae (P.); Andrew Maguire (P., M.); Frank Needham Marsh (M.); William Aikman Muir (M.); Charles Sutherland M'Kay Murison (M.); Watson Noble (P., M.); Ralph Montgomery Fullarton Picken, B.Sc. (M.); Richard Rae (M.); Henry Nimmo Rankin (M.); Hugo Given Robertson (P., M.); Allan Semple (P., M.); James Brown Sim (M.); William Stevenson (M.); Hugh Cochrane Storrie (M.); David Taylor (M.); Walter Telfer (M.); Arthur Turnbull, M.A., B.Sc. (P., M.); Hugh White (M.); David M'Gruther Wilson (P.); John Alexander Wilson (P., M.); John Youngson Wood (M.); Hugh Young (M.). Women.—Margaret Baird Sproul Darroch (M.); Olive Robertson (M.); Winifred Margaret Ross (M.); Jeanie Hinshaw Stewart (M.).

The following passed with distinction in the subjects indicated:—

Second Examination—In Anatomy—William Howat, M.A.; Alexander Leishman. In Physiology—John Allan Munro Cameron; Jeanie Douglas M'Whirter, M.A. In Materia Medica and Therapeutics—Edward George Glover; John Granger; William M'Adam, M.A.; John William M'Nee; Hyacinth Bernard Wenceslaus Morgan.

Third Examination—In Pathology—Arthur Turnbull, M.A., B.Sc. In Medical Jurisprudence and Public Health—Matthew Ignatius Thornton Cassidy; Francis William Mackichan; Ralph Montgomery Fullarton Picken, B.Sc.

NOTICES TO CORRESPONDENTS, &c.

☛ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Scotsman.—No official figures are furnished, but it is said that the Royal College of Physicians of London and the Royal College of Surgeons of England receive yearly about £12,000 in examination fees between them; of this amount about £8,000 goes to the examiners.

M. T.—We believe Southwark is the only London borough that favours compulsory notification of tuberculosis. At a recent meeting of the Borough Council the matter was dealt with. They then decided to make it a compulsorily notifiable disease. The Progressives argued that the new order would result in many men having to give up their employment, especially in view of the new Workmen's Compensation Act.

Seaside.—Yes, even shrimps are preserved with boracic acid. A shell-fish dealer was summoned at Southport only the other day for selling potted shrimps containing an excess of boracic acid. For the prosecution, it was stated that the pot of shrimps contained 107.6 grains of boracic acid to the pound. It was stated that the Corporation intends to prosecute in all cases in which the amount of boracic acid as a preservative exceeds 35 grains to the pound. For the defence, it was stated that the defendant had purchased the shrimps from a wholesale potter, who, owing to the scarcity of shrimps at Southport, had bought them at Manchester and had potted them exactly as received. The Bench inflicted a fine of 20s. and costs.

Occupation.—The total number of cases of poisoning and of anthrax reported to the Home Office under the Factory and Workshops Act during August was 58, there being 48 cases of lead poisoning, 2 of mercurial poisoning and 8 of anthrax. In addition to the above, 17 cases of lead poisoning were reported among house painters and plumbers. During the eight months ended August, 1907, the total number of cases of poisoning and of anthrax was 376, as compared with 484 in 1906. The number of deaths during the same period was 28, as against 36 in 1906. In addition there were 104 cases of lead poisoning (including 26 deaths) among house painters and plumbers in the first eight months of 1907, as compared with 111 (including 26 deaths) in the first eight months of 1906.

Meetings of the Societies, Lectures, &c.

Wednesday, October 16th.

Royal Microscopical Society (20 Hanover Square, W.).—8 p.m.: Papers:—Mr. A. A. C. E. Merlin: (1) Note on a New Prismatic Microscope Ocular; (2) On Ghost Images seen in the Secondaries of Coseinodiscous Asteromphalus.—Mr. A. Letherby: Systematic Exposure with Transmitted Light in Photomicrography.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. A. H. Tubby: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. B. Abrahams: The Post-Influenzal Heart.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Thursday, October 17th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. H. Evans: Cysts and Cystic Conditions of the Neck.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson), X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture:—Mr. J. Cantlie: Recent Discoveries in Tropical Medicine.

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Eczema (its Varieties, Symptoms, and Causes).

Friday, October 18th.

Society for the Study of Disease in Children (11 Chandos Street, Cavendish square, W.).—5 p.m.: Cases will be shown by Mr. S. Stephenson, Dr. Chisholm, Mr. G. Pernet, Mr. L. Mummery, Dr. Langmead, and others. Paper:—Dr. E. C. Williams: On the Simulation of Some of the Symptoms of Primary Amaurotic Idiocy by a Cerebral Tumour.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. H. W. Dodd: Clinique. (Eye.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Central London Throat and Ear Hospital (Gray's Inn Road, W.C.).—3.45 p.m.: Demonstration:—Mr. C. Nourse: Larynx.

Appointments.

Carlyle, Oliver, L.R.C.P. and S. Edin., House Physician and Pathologist at the Infirmary, Sunderland.

Chapel, K., M.B., B.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Rothwell District of the county of Northampton.

Cunliffe, E. N., M.D.Vict., M.B., B.S.Lond., M.R.C.P.Lond., Honorary Consulting Physician to the Colne Cottage Hospital.

Cunningham, Richard G., M.B., Ch.B., Senior House Surgeon at the Infirmary, Sunderland.

Dodds, Thomas George Boswall, M.D., B.Ch.Edin., Medical Officer to the Starcross (Devon) Branch of the Rational Association Friendly Society.

Fitzgerald, C. C., L.R.C.P. and S. Edin., L.F.P.S.Glasg., Junior Assistant Medical Officer at the Hope Hospital Union Infirmary, Salford.

Granger, Henry, M.R.C.S., L.R.C.P., Resident Medical Officer at the Royal Victoria Hospital, Bournemouth.

McLean, Murdo, M.A., M.B., Ch.B.Edin., House Surgeon at the Infirmary, Sunderland.

Vacancies.

Brighton, Hove, and Preston Dispensary.—House Surgeon. Salary, £160 per annum, with furnished rooms, coals, gas, washing, and attendance. Applications to C. Somers Clarke, Hon. Secretary, 113 Queen's Road, Brighton.

North Riding Lunatic Asylum, Clifton, York.—Junior Assistant Medical Officer. Salary, £150 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Woodilee Asylum, Lenzie.—Medical Officer. Salary, £150 per annum, with board, lodging, etc. Applications to Dr. Marr, Medical Superintendent.

The Finsbury Borough Council.—Medical Officer of Health. Salary, £600 per annum. Applications to G. W. Preston, Town Clerk, The Town Hall, Rosebery Avenue, E.C.

City of Birmingham.—Assistant Medical Officer of Health. Salary, £250 per annum. Applications to the Chairman of the Health Committee, Council House, Birmingham.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary, £150 per annum, with apartments (not board). Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23, Castle Street, Carlisle.

Edinburgh District Asylum, Bangour Village.—Second Assistant Physician. Salary, £120 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent, Bangour Village, Uphall.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary, £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

Births.

Fawcett.—On Oct. 9th, at High Park, Roscrea, Ireland, the wife of Edward Fawcett, M.D., of a son.

Thompson.—On Oct. 5th, at Tutshill, Chepstow, the wife of Cecil C. B. Thompson, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

Hunton—Young.—On Oct. 9th, at the Parish Church, Great Stainton, Frederick Hunton, M.D., of Sedgefield, to Eleanor Mary, daughter of the late William Joseph Young, J.P., D.L., of Wolviston Hall, Stockton.

Moore—Ravenscroft.—On Oct. 9th, at the Parish Church, Ewell, Surrey, John William, youngest son of the late R. H. Moore, F.R.C.S., Dublin, to Violet Hastings, only daughter of the late Honble. W. H. Ravenscroft, C.M.G., of Ceylon.

Mulkern—Voules.—On Oct. 8th, at St. Mary's Church, Wootton, Bedfordshire, Hubert Cowell Mulkern, M.D., second son of Alfred Courtney Mulkern, to Florence Emily, only daughter of the late Laurence Francis Voules.

Robinson—Ward.—On Oct. 8th, at Swanage Church, Gerald C. F. Robinson, F.R.C.S., son of Gerald Robinson, Esq., to Helen Margaret, elder daughter of Lieut.-Colonel A. C. Ward, late R.E.

Verling-Brown—Hair.—On Oct. 9th, at St. Peter's Church, Belsize Park, N.W., Charles Richard Verling-Brown, M.D., Lond., of Sutton, Surrey, elder son of the late Charles Brown, of "Carnarvon," Bournemouth, to Jane, younger daughter of J. Hair, Esq., of Hampstead.

Deaths.

Dredge.—On Oct. 8th, at Melrose, Glastonbury, Captain J. A. Dredge, I.M.S., Staff Surgeon at Bangalore. (Accidentally killed out riding.)

Elliott.—On Oct. 6th, at Hull, George Frederick Elliott, M.D., F.R.C.P., England.

Heath.—On Oct. 4th, Edward Alfred Heath, M.D., of 34, Ebury Street, London, and Shoreham, Kent, aged 68.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, OCT. 23, 1907. No. 17

NOTES AND COMMENTS.

Defeat of Southend.

SOUTHEND is emerging ignominiously out of its contest with its medical officer of health. As the result of the attitude of loyalty to their colleague taken by medical men generally, the advertisements issued by the Southend Town Council only elicited four replies from applicants for the post, and not one of these was suitable. Considering that when Dr. Nash was originally appointed a few years ago there were forty-eight applications, most of them presumably from qualified men, it cannot be said that there is no cohesiveness in the profession when a question of principle is at issue. Whatever the unfortunate dispute has or has not done, it has at least shown that there is now a fairly well organised *esprit de corps* among medical men, and that this spirit is a factor to be taken into consideration by public bodies who try to play fast and loose with their medical officials. On that let us at least congratulate ourselves, for in the case of medicine it is as true as ever it was, that united we stand, divided we fall. We do not envy the Health Committee of Southend their position, for they themselves are aware of Dr. Nash's value and uprightness, and yet, acting under the orders of the Council, they have to find a successor to him in face of a practically unanimous boycott by the medical profession. At present matters stand thus. Finding no suitable man can be obtained for the post, the Health Committee were bound at the last meeting to recommend that Dr. Nash should be re-appointed for another year at the proper salary, namely, £600 a year, and of course this proposal was very distasteful to the Council, especially to those members who had come into conflict with Dr. Nash through their own sanitary shortcomings. Needless to say, the recommendation was opposed in every way, but it had perforce to be carried eventually, the only modification being that the period of re-appointment was shortened to nine months.

The Need for Inquiry.

Now this period, it seems to us, is quite long enough for the question to be thoroughly investigated by the Local Government Board. The health of Southend and the efficiency of the health administration of the whole country is bound up in its settlement. Mr. Burns, with his long experience of local authorities, and Dr. Macnamara, by his recent declarations, are both fully alive to the unsatisfactory and anomalous position in which health officers are placed by the insecurity of their tenure, and they must know that in the result hundreds of wrongs that need righting are untouched, because the very man who could tackle them is unable to act without risking the loss of his livelihood. The Southend case would make an admirable subject for a public inquiry by the Board, because it contains the elements which compose all difficulties of the kind, *plus* a medical officer of more than usual enterprise, and one who preferred his duty to soft words and ineffectiveness. If the Local Government Board leave things where they are, it is possible that the Council will be able to secure a medical officer at the end of the nine months, and the present fight will be in vain. On the other hand, if they hold an inquiry now, and, being satisfied as a result that Dr. Nash has been punished for doing his duty, intimate that they will not sanction any variation in the terms of his appointment, Southend will serve as a lesson to the rest of those sanitary authorities who set personal interests above public ones.

Cheltenham and its M.O.H

As a matter of fact, at the moment a similar fight is engaging the Council of Cheltenham. Dr. Garrett, the medical officer of health of that borough, is an energetic and well qualified man, who has raised the reputation of Cheltenham as a health resort to a high level. Unhappily, his care for the town has brought him into collision with the butchers, or certain butchers, whose slaughter-houses he has opposed, and with other parties whose private interests are not coincident with those of the public. Now, it is as inevitable that a conscientious medical officer of health should find himself in collision with private tradesmen as that a conscientious policeman should occasionally find himself under the painful necessity of injuring the feelings of Bill Sykes; human nature being what it is, there will always—this side of the millennium—be bad landlords, erring tradesmen, and incorrigible rogues. A medical officer who did not find any nuisances to abate would be as slack or incompetent as a policeman who found no thieves, but whereas society congratulates the policeman on his success, the medical officer (usually) gets kicks. The Cheltenham Town Council is being asked to reduce Dr. Garrett's salary by £100 a year as a reward for his energy and competence, and while we hope they will have nothing to say to so monstrous an injustice, we may, with some confidence, point to Southend as an example of what may happen if they give way. Happily, however, in the case of Cheltenham the Local Government Board have the last say in the matter.

Ici on parle Français.

THE line between legitimate and illegitimate advertising by medical men is so delicate a one that till the end of the chapter there is likely to be an infinity of disputes with regard to it. Whereas there are, unfortunately, members of the profession who stretch the elastic boundary to breaking-point, it cannot be denied that there is in some quarters a hyper-sensitiveness with regard to prominence attained by professional brothers. The important point to remember about medical rules is that they are laid down for the benefit of the public, and that medical etiquette is made for the man, and not man for etiquette. An amusing example of this hyper-sensitiveness has just occurred in Saxony, where the Medical Council of that State has decreed that it is derogatory to the dignity of medical men for one of them to indicate on his door-plate that he can speak English and French! Now, to a patient in a foreign town it may certainly be a deciding factor in selecting a doctor that he can speak the patient's native language, but who can say that such a reason is not perfectly legitimate? It must be convenient to foreign visitors to a town to know which doctors can be expected to understand them when they explain their symptoms, and which ones can merely, with strained sympathy, ejaculate "Ach" or "Ja." We can imagine that the General Medical Council would not smile if it became the fashion to adorn the dining-room windows in Harley Street with white letters announcing "Ici on parle Français," or "American Understood," but it would certainly be comforting for a man taken with abdominal pain in Naples to see "English spoken" on Signor Baccelli's plate.

German Legislation and its Consequences. THE recent German legislation prohibiting advertisements of quack medicines has caused some fluttering in the dovecotes of the gentlemen who live by that obnoxious trade. The *Advertising World* describes the legislation as grandmotherly, because it considers the German people the best educated in the world, and therefore able to "act with intelligence and discrimination." It seems to us that they have just given a signal proof of this ability by prohibiting advertisements which appeal solely to the ignorant and fleeceable members of the community. A correspondent of that journal, Mr. Robert Glasspole, of Coventry, writes to the editor an interesting and significant letter objecting to the comments made by him on this legislation. In the course of this letter Mr. Glasspole says: "I do not hesitate to express the opinion that sooner or later something will be done in this country, having the same object as that held in view by the German legislators when they made their law affecting patent medicines. Lest it should be thought that my argument is disinterested, I might say that I am myself an advertising man, and happen to know how, in some of the most notable instances, the copy issued (including the testimonials) is originated. As tending to show that I am not alone in my opinion, even amongst those connected with advertising, I should mention that in the advertisements of one of the most progressive advertising agencies in this country, there appeared not long ago the announcement that contracts for patent medicines would not be accepted." It is particularly striking that such strong and sane views should be held by a gentleman who is an advertising man himself, and we are thankful to know that there is at least one agency which will not lend itself to the duplicity and frauds of the quack medicine trade.

Retirement of Politzer. THE retirement of Professor Politzer, of Vienna, is an event of considerable interest, for he is acknowledged generally to be one of the pioneers of otology, and he has undoubtedly the highest international reputation of any practitioner of that branch of surgery. Professor Politzer owes much of his success to his ingenuity and to his manual dexterity. The latter he acquired in his early days as a painter, an art in which he earned no little skill and renown, and his originality of thought and method after devoting himself to otology are known all over the medical world. For thirty-six years he has been professor at Vienna, and it was only the other day that he brought out his enormous work on his speciality. The good wishes of many sufferers, and of all his medical colleagues, will follow him into his well-earned retirement.

LEADING ARTICLE.

THE ADMINISTRATION OF ANÆSTHETICS IN HOSPITALS.

THE points recently raised by the City of London Coroner, Dr. F. J. Waldo, have clearly enough an important bearing on the administration of anæthetics, as regards both the public and the medical profession. An inquest, as most of our readers are aware, was held on the body of a woman who died at Guy's Hospital some ten or fifteen minutes after the administration of chloroform was commenced by a house surgeon. The patient was suffering from exophthalmic goître, and the operator had just made the first incision, when the patient vomited slightly, or attempted to vomit, and then ceased breathing. It appears that the operation was performed at the day and hour usually fixed for such procedures, so that there was ample time to make the necessary preparations and to secure the attendance of one of the eight staff anæsthetists attached to the hospital. As regards this particular occasion, both the surgeon and the house surgeon admitted in evidence that they recognised that operation in cases of exopthalmic goître involved special anæsthetic difficulties. There is no need in these columns to dwell upon the peculiar risks involved therein in the position of the neck, the occasional pressure upon the trachea, the hypersensitive nervous mechanism concerned, and the frequently enlarged thymus. The point to be considered, however, is whether, with all these facts in view, any system can be countenanced which permits a house surgeon, whose experience is limited to some ninety or one hundred administrations, to give the anæsthetic, in spite of the fact that more experienced anæsthetists are available. At the inquest the house surgeon accepted all responsibility, but it may be doubted whether the public or the medical profession would approve such an assumption. Legally, we believe the responsibility rests with the operator, and in this particular case the surgeon said he was ready to accept part of the responsibility. The Coroner thereupon naturally pointed out that a man who was undertaking a difficult operation could not be expected at the same time to superintend the anæsthetic. The inquest thus centres upon the system in vogue at Guy's, and, for that matter, at many other hospitals throughout the kingdom. It is often a matter of convenience to the surgeon and to the hospital surgeons to have an anæsthetic administered on the spot by one of the resident staff. In many small institutions and country places it is absolutely the only course open to the operator. Nor in any big hospital would it be possible in a large number of surgical casualties to call in the services of a special anæsthetist. On the other hand, if there be any virtue at all in specialism in the administration of anæsthetics, not to mention staff appointments of that kind, it seems abundantly clear that special anæsthetists should attend all difficult operations where due notice can be given. The education of the student can be equally well, or probably far better, conducted by practical demonstration or by supervision than if he be left to his own unaided resources. It is of course necessary to instruct medical students in the administration of anæsthetics, which they are called to administer in after life under many varied circumstances, at times involving the assumption of the highest possible degree of direct personal responsibility. But while the necessity for a practical training must be freely admitted, it may, nevertheless, be a matter of question whether this or that given system of training is not open to improvement. In many ways the question of anæsthesia is of as much direct importance to the success of an operation as well as to the safety of the patient as the actual surgery which is involved. From this standpoint we venture to doubt whether sufficient importance is attached to the subject of practical anæsthetics in the medical curriculum. So far as the after career of the medical practitioner is concerned, we have little hesitation in saying that he would be better equipped for the battle of professional life by a sound education in anæsthetic administration than by the study of technical experimental physiology and other highly specialised branches of scientific work having a more or less indirect bearing on medical practice. So far as Guy's Hospital is concerned, we have no doubt that the authorities will take immediate steps to review the situation and to introduce any alterations in the present system that may appear necessary or desirable. An institution of that standing is so far above suspicion that no reasonable person would blame the authorities were any administrative defect shown to exist. At the same time, it must be borne in mind that all human organisations are fallible, and that with increasing knowledge and experience reforms are necessary from time to time if they are to keep abreast of the progress of knowledge and experience. In our opinion, the time has arrived when, in the interests of the community, an authoritative Government enquiry is demanded into the whole question of anæsthetics and their administration. We further think that such a Commission, to be of real value, should be constituted not solely of medical men, but of men eminent in science generally, of lawyers, and of others of acknowledged intellectual standing, in conjunction with a few medical men. Comparative statistics of all large hospitals should form an important feature of the evidence before such a Commission.

THE DEADLOCK AT THE ROYAL BRISTOL INFIRMARY.

The conflict of opinion that has arisen between the staff and the Board of Management of the Bristol Royal Infirmary shows little sign of settlement. In its essence the dispute becomes one of the right of a medical charity to say what outside duties may or may not be undertaken by its honorary medical staff. There is obviously something to be said on both sides of the question. If the Board finds its medical staff performing outside duties of such a nature as to interfere with the attention due, in the first instance, to the patients of the Royal Infirmary, it has clearly a right to expostulate and, if necessary, even to revise the terms of an appointment the duties of which are perfunctorily performed. We are glad to believe, however, that such a hypothetical case would be of the very rarest occurrence in the medical profession. Any physician or surgeon finding his energies unduly drawn upon by an auxiliary appointment would naturally resign, not less as a duty to himself than to his colleagues and to the medical profession outside the walls of the hospital. It would be useless to attempt to disguise the fact that plurality of appointments is open to serious abuses. Perhaps one of the greatest objections is that the pluralist, while holding a position to which he is personally unable to do justice, is, at the same time, excluding one of his own cloth from the higher things that undoubtedly attach to hospital life. So far as the Bristol Royal Infirmary is concerned, the medical staff have acted with commendable firmness and moderation. The new regulations passed by the governors—but not yet confirmed—provide that no member of the full staff shall hold any other professional public appointment except professorship or lectureship at any university, college or school; further, that only consultant or special practice shall be permitted. The medical staff accepted the latter clause, but have refused to acquiesce in the former, and have intimated that, in the event of its being retained, they will have reluctantly to send in their resignations. It would be a matter of profound regret were the outcome of these attempted changes to end in so disastrous a fashion. After all said and done, the services of the medical staff are purely honorary, and it is surely for themselves to regulate their own professional lives. While it is quite reasonable and, indeed, salutary that the governors of a charitable institution should be able to satisfy themselves at any moment that the work of the hospital is being conducted in the best interests of the public, we can by no means agree with the arbitrary and unconstitutional interference with the extramural rights of their honorary staffs. For the present the matter is in abeyance, but it will come up shortly for a final decision by the governors of the Bristol Royal Infirmary. It is impossible to think that the governors, without overwhelming evidence of the necessity of such a step, will estrange and eliminate their present staff by adopting rules that are condemned by the whole of the local medical practitioners, and thus reverse a policy under which the Bristol Royal Infirmary has for many generations faithfully and honourably discharged a great public responsibility.

Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee on the 11th inst., the investment of about £7,000, the surplus produced by the Society's operations through the summer, was arranged. The rate secured was 3¾ per cent., and this leaves a large margin over the rates assumed when the business of the society has been valued. The funds of the society now amount to over £215,000, of which £14,000 is treated as an investment reserve to cover any fall in the price of the Stock Exchange Securities held by the society, or any losses that may be incurred in any other manner.

CURRENT TOPICS.

The Alleged Dearth of Medical Men.

As a general statement, there seems little doubt that there has been for some years past an increasing difficulty in finding men to take junior resident posts in hospitals and other medical institutions. The rush of applicants, however, for adequately-paid appointments is just as great as ever, and the obvious deduction is that advantage has been taken of an overcrowded and disorganised profession to cut down salaries below a fair standard. A Manchester practitioner has recently written to a local newspaper, stating that not long ago he advertised for an assistant in his practice, and received no fewer than ninety-three replies, of which eighty came from suitable persons. We do not say what salary he offered, but we may infer that it was adequate to the purpose, judging from the result. The same correspondent appended an analysis of forty-four posts offered in a leading medical journal for medical men, the average remuneration being £90 per annum, with board and lodging. He remarks that, rather than spend £1,000 on educating a son of his to enable him to earn £90 yearly, it would be better to make him a bricklayer, as he might then perhaps live in comfort on such an income. The protest is vigorous, but is in itself hardly likely to contribute materially towards reform, unless, indeed, it suggests to hospitals which fail to secure residents that they should henceforth offer an adequate salary. The medical profession will never be able to secure fair remuneration until it is protected against the unfair competition of quacks and quackery; nor, it may be remarked incidentally, will the public safety and the national stamina be safeguarded until this elementary precaution be taken by the legislature.

Spotted Fever as a Test of Local Sanitation.

THE gospel of disease prevention could hardly find a finer text than that afforded by the recent report of the Local Government Board for Ireland upon "spotted fever" in Belfast. Dr. Clibborn, the inspector, attributes the outbreak to an infected coalheaver working on one of the ships from the Clyde. From the visit of that single patient sprang an epidemic of 233 cases, of which no fewer than 154 were fatal. This occurrence shows the enormous importance of an efficient system of port inspection. Although it would be a counsel of perfection to attempt to exclude all cases of minor infection, yet it is nevertheless possible to insist upon proper reports from the ship authorities, and a compulsory medical examination of all persons who are obviously ill. But the lessons of the Belfast outbreak by no means end with the necessity of port sanitation. The fact stands out in high relief that the disease establishes its foothold in filthy houses, and is propagated by actual human contact. Although there is much to be learnt with regard to the specific microbe of "spotted fever," we know that it cannot live long enough outside the human body to be propagated in dust, furniture, bedclothes, and so on. The moral is obvious. This terrible disease can flourish only in communities which permit the continuance of plague spots within their walls. As with some other communicable diseases, "spotted fever" could gain no grip in any district kept up to a reasonably high pitch of sanitary perfecton. Viewed from this standpoint, the extent and duration of an outbreak of the malady in question may be regarded as a kind of test imposed by Providence upon the sanitation of any given locality.

Some Medical Aspects of the Shrewsbury Railway Accident.

ONCE again the British public has been startled by a terrible accident to an express train. It seems likely that it will never be known why the train ran into a dangerous curve at such excessive speed, but the probable explanation appears to be that the brakes failed to act. The tragic fate that has overtaken so many of our fellow-countrymen suggests that it would be well to raise some obvious medical considerations at the present moment. The necessity of periodical inspection of the engine-men and guards has been often insisted upon in medical journals. One has only to reflect on the terrible consequences that may result from a momentary lapse of reason or attention on the part of an engine-man or a guard, to realise the need of full sanity of mind and body. Perhaps one of the points upon which the medical profession could insist with most advantage is that concerning the long hours of railway-men. It is absolutely impossible for an habitually over-worked man to keep his attention concentrated continuously upon his work. It is the momentary oblivion of the driver or the signalman that does the mischief. Parliament might do worse than appoint a medical commission of enquiry into the hours of railway-men, or, at any rate, a commission in which the profession of medicine would be strongly represented.

Army Reform and the Medical Profession

IN the scheme for the reform of the Territorial Army, which was foreshadowed by Mr. Haldane in his speech at North Berwick last week, a reference was made to the assistance which he hopes to get from the medical profession. So far as can be made out from Mr. Haldane's brief sketch, it is intended to reorganise a medical force for the Territorial Army on lines similar to those on which the Royal Army Medical Corps runs for the Regular Army. This Territorial Medical Service will be wanted, in time of war, not only to treat wounds but to secure sanitation and health preservation. The various medical units which are necessary will be raised, as far as possible, within the areas in which the divisions are formed. Outside these units the co-operation of experts in preventive medicine will be invited, whose advice will be asked in time of war, should troops be massed in their neighbourhood. Undue demands will not, however, be made on their time, and there will be nothing in any part of the scheme to interfere with the civil occupations of those taking part in it. It is, of course, impossible to criticise Mr. Haldane's scheme until we know something more of it in detail. At the same time, there is no doubt that it is a good intention to interest members of the medical profession throughout the country in national defence, so that they may prove of use in the event of war. Mr. Haldane may be assured of the active support of members of the profession in the carrying out of any sound scheme.

Milk Contamination.

It is not long since that our countrymen stood aghast at the horrors of the American tinned meat factories. It now appears that they may have their fill of that sort of thing without going across the Atlantic; indeed, by simply turning to the milk can at their own doors. A London milkman was recently charged on a warrant with selling unwholesome milk. The Westminster Medical Officer of Health deposed that the milk seized from prisoner had a number of black smuts floating on its surface: the fluid smelt offensively, and there was a large quantity of filthy material at the bottom of the can. This sediment was found to contain a large quantity of vegetable and other débris, consisting of hairs—some human and others belonging to small animals—pieces of human skin, and other most objectionable matter. The refuse apparently came from a dirty stable or the street, and it may be conjectured that some of it was due to dipping out the milk with a dirty can. The milkman cynically suggested it was due to the fog, but that defence did not save him from a sentence of six months' hard labour. This heavy punishment should act as a warning to the milk trade. The patience of the public must soon be exhausted, and fresh legislation will be demanded to stop the noisy carts of the milkmen, their adulterations, and their traffic in milk of tuberculous cows, all of which constitute offences of a nature that would not be tolerated for a moment in the case of other tradesmen.

Specific Cruelty in Divorce.

The legal interpretation of "cruelty" is somewhat elastic and fanciful, a fact that to some extent indicates the insufficiency of the existing law. The communication of venereal disease to a wife has happily long ago been included within the category of cruelty. Moreover, the advance of medical science has now made it possible to produce absolute evidence in the shape of bacteriological proof of the existence of both syphilis and gonorrhœa. From a recent judicial utterance it may be gathered that the mere fact of specific infection of the kind mentioned constitutes a sufficient ground for divorce, apart from any further question of legal cruelty. Mr. Justice Bucknill, however, in the course of the recent hearing of a painful case of the kind from Nottingham, made an important judicial utterance upon the subject. After commenting upon the present state of the law, he added that, in his opinion, it ought to be made a criminal offence for a man wilfully to communicate a specific disease to his wife. The Medical Press and Circular goes a good deal further than that, and maintains that it ought to be made a criminal offence for any man knowingly to communicate a venereal disease to a woman, or vice-versâ, on the absolutely clear and definite principle adopted by the legislature in the case of ordinary specific communicable diseases. Why punish a man for spreading small-pox but not the wanton dissemination of syphilis?

The Sheffield Infirmary Appointments.

We learn that the Sheffield Guardians propose to appoint as Medical Officer of the hospital a gentleman with greater experience, who will be able to take full control of the medical work. There will be two junior officers as before. They do not propose filling the position of visiting surgeon and visiting physician vacated by Dr. Wilkinson and Dr. Arthur Hall. But that will not prevent the Hospital Committee calling in outside aid whenever it is required for surgical operations. The new Medical Officer will be paid a salary of £300. It is understood that the Local Government Board representatives who recently visited the Workhouse Hospital fully approve of these changes.

PERSONAL.

H.M. the Queen has sent a donation of 600 guineas to the London Hospital.

Dr. Borger has been appointed personal physician to the King of Siam.

Mr. A. H. Lees has been appointed to a Research Studentship in Medical Entomology at Cambridge.

Mr. Rushton Parker has resigned his post of senior surgeon to the Liverpool Royal Infirmary, his term of office having expired.

Mr. Nathan Strauss, of New York, has offered a pasteurising plant to the cities of Dublin and Liverpool, in connection with their scheme for reducing infantile mortality.

Mr. Joseph Montagu Cotterill, M.B., C.M.Edin., F.R.C.S., was unanimously elected President of the Royal College of Surgeons, Edinburgh, on Wednesday last.

Mdme. Zola has presented to the Assistance Publique of Paris her house and grounds at Medan as a convalescent home for infants. Dr. Méry has been appointed physician to the establishment.

Dr. Koch, who has been examining the causes of sleeping sickness, left Mombasa for Germany on October 15th. His investigation camps in Uganda have been taken over by the colonial authorities.

Mr. Victor Thomas Ellwood, of Merchant Taylors' School, has been elected to the Medical Scholarship instituted at Pembroke College, Oxford University, by Dr. Theodore Williams.

Dr. T. Sangster Greig has been the recipient of a handsome testimonial from the staff of the West Ham Infirmary. Dr. Greig has been Acting Medical Superintendent of the Institution for some time, and has failed to be elected to the post permanently.

The friends and pupils of Dr. Hallopeau are subscribing for the presentation to him of a medal, executed by M. Chaplain. The list is open till November 10th, and all subscribers of twenty-five francs will receive a replica of the medal.

Dr. Edward W. Hope, Medical Officer of Health for Liverpool, and Professor of Public Health in the University of Liverpool, delivered an address on "Some present problems of public health administration" at the inaugural meeting of the York Medical Society last week.

Dr. Edgar Byass, of Cuckfield, who, for health reasons is leaving the district, has just been presented with a handsome parting gift of £417, together with a bound list of the subscribers. The Byass family have been associated with medical practice at Cuckfield for over 100 years.

A CLINICAL LECTURE

ON

URÆMIC MENINGITIS. (a)

By PROFESSOR R. LEPINE, M.D.,

Of the Lyons Faculty of Medicine.

Is there such a thing as uræmic meningitis? Pericarditis, as a complication of uræmia, is frequently observed, and whether it be a direct effect of the toxæmia or, as some hold, invariably the result of infection, the fact remains that the renal subject offers a favourable soil for its evolution. One thing is certain—*viz.*, that pericarditis becomes more frequent the nearer the approach of the uræmic state. Theoretically, therefore, I see no obvious reason why the meninges should not sometimes be affected like the pericardium.

I have not been able to find anything in medical literature bearing on the question, but three cases which have recently come under my observation suggest the possibility of such a relationship, and this I propose to discuss in the light of the information they afford.

The first patient was a labouring man, æt. 65, who had for some time previously been suffering from arterio-sclerosis, and was re-admitted in March with well-marked symptoms of kidney disease, and, in particular, general anasarca. Subjected forthwith to the dechloridation treatment, his state did not improve, and early in May he became delirious. He was still passing a fair quantity of urine (about four pints), but this was highly albuminous, and the elimination of methylene blue was greatly below normal. Little by little the uræmic condition became more marked, consequent upon the gradual failure of the heart. The pulse, which had been bounding (without any double murmur), became weak, and he died on May 31st, without either convulsions or coma.

Post mortem, the kidneys weighed 8½ ounces. The cortex was much atrophied, and the large, flaccid heart, more dilated than hypertrophied, weighed 20 ounces. The meninges over the convexity of the hemispheres were thickened, and were milky white except at one spot two or three inches square, which was bright red. The meninges were easily stripped from the subjacent grey matter, which was healthy, with the exception of a small patch of softening in the temporal convolution. The central parts of the brain were quite healthy.

No trace of tubercle was discovered in any of the organs or tissues, or cicatrices suggestive of healed tuberculosis.

The patient was reported to have been of sober habits, so that the thickening of the meninges could not have been due to alcohol. Its existence might be secondary to the renal condition, for during his two months' sojourn in hospital no other cause had intervened. To this acute process and the toxæmia the delirium was no doubt due, for the patch of softening did not appear to have played any part in its production.

Case 2 was that of a woman with kidney disease who developed delirium and sundry meningeal symptoms, and in whom, post mortem, the meninges were found to be of a bright red colour. She was æt. 45, and was brought to the hospital by neighbours, who knew very little about her history. She was very thin, had a vacant look, and could not be got to speak. She appeared, however, to understand to some extent what was said to her. There was no stiffness, and Kernig's sign was absent. The reflexes were exaggerated. Pulse 116, some rhonchi in both lungs. The urine, withdrawn by catheter, was of normal colour and albuminous. Lumbar puncture gave issue to a clear fluid. An enema brought away a large motion, without any improvement in her state.

The next day the heart beat was 128, with a tendency to gallop. The urine, mostly passed involuntarily, was darker and contained 17 per cent. of urea and the merest trace of albumen. There was some difficulty in swallowing, the face was turned to the right, the pupils were sometimes contracted, or at other times normal, the left being the larger. Respiration was noisy, but regular; the abdomen was soft. Examination of the urine on the 16th showed a marked diminution of phosphoric acid in proportion to the urea. A second lumbar puncture gave issue to fluid under moderate pressure (whereas on the previous occasion the pressure appeared to be high). Nothing particular was found therein. Post mortem, the atrophied kidneys weighed 3¾ ounces, while the heart weighed 12½ ounces. There was some cicatricial tissue in the apex of one lung that was probably of tuberculous origin. The cerebral meninges were much injected over the convexity, and several convolutions presented a bright red colouration. The cerebral ventricles were not dilated. No trace of exudation.

Case 3 was that of a young woman, æt. 30, admitted on May 12th. She was restless and delirious and had visual hallucinations. The rectal temperature was 104° F. Dr. Rome, who had been attending her, gave us the following particulars:—Her father, a chronic inebriate, died of ethylism at the age of sixty. She had lost a sister of meningitis at twenty-two. No tuberculosis in the family. She was spare, but healthy, was of sober habits, and lived a regular life. She had lost her mother five months before, and since that time she had become irritable, and for two months had suffered from headache. The actual attack had set in eight days before admission, with shivering that obliged her to keep to her bed. She remained in bed the following day on account of a "stitch" in the side. The temperature was high and the dyspnœa very pronounced. Dr. Rome was called in on the 11th, when respiration was rapid, there was slight dulness at the right base, with tubal breathing and crepitant rales. Pulse 130. Consciousness dulled. Violent delirium all night, and next day she was brought to the hospital.

At this stage the breath signs were barely audible at the right base, and the two symptoms that attracted our attention were the delirium and the retraction of the abdomen. No stiffness, no Kernig's sign, no exaggeration of the reflexes. Pulse 130.

On the 13th she was calm but unconscious. Some stiffness of the neck was noted and Kernig's sign was well marked. Lumbar puncture gave exit to a perfectly clear fluid, under a certain degree of pressure, containing a few lymphocytes and an occasional polynuclear cell. The physical signs at the right base had disappeared. The abdomen was still concave. Temperature barely 99.5° F. It fell the next day to 98° F., with a slow pulse. The patient vomited for the first time, and became comatose. Death took place on the 15th. Post mortem, the kidneys were found to be the seat of chronic nephritis and weighed 7¼ ounces. The heart weighed 11½ ounces. There was general congestion of the viscera. At the apex of one lung a few white spots were seen, which, however, did not look like grey tubercles. There was no trace of past tuberculous mischief.

(a) Delivered at the Hotel Dieu at Lyons.

The meninges were intensely red, with marked congestion of the cortex. Nothing was found at the base of the brain.

Careful examination of the apices of the lungs revealed nothing pointing to tuberculosis. The kidneys presented the characteristic lesions of vascular origin. A certain proportion of the arteries presented somewhat advanced lesions of arteritis and periarteritis. The case, then, was one of Bright's disease, with what appeared to be inflammatory redness of the meninges, limited to the convexity, without exudation or tuberculous granulations.

It is to be noted that this patient, on admission, presented a herpetic eruption on the lip. I have already pointed out that the broncho-pneumonic lesions did not present the histological appearances of the tuberculous process, and Ehrlich's diazo-reaction, which is always positive in tuberculosis, proved negative here.

The existence in the second case of old-standing lesions pointing to past tuberculous disease of the apex may suggest a tuberculous origin of the meningeal congestion, but these lesions gave one the impression of being quite "dead," and the low temperature militated against any such hypothesis. Lastly, a close examination of the meninges failed to reveal the slightest trace of granulations.

I do not, of course, pretend that tuberculous infection is necessarily associated with the presence of granulations. The nature of a given lesion is to a certain extent independent of the anatomical characters which it displays. This is an unquestionable fact upon which, in respect of tuberculosis as it happens, Prof. Poncet has very properly insisted of late. But for the above reasons it appears to me highly improbable that there was anything tuberculous in either of the two female patients just referred to. I may add that the rapid course of the malady, the freedom from disease of the base of the brain, and the absence of any meningeal reaction in the cerebro-spinal fluid, are points to be borne in mind.

To sum up, the first patient presented marked thickening of the meninges over the convexity, apparently due to the uræmia. In the two others the symptoms pointed to meningitis, and recent lesions were discovered. Unfortunately, owing to circumstances beyond our control, no histological examination of the meninges was made, so that we are not in a position to speak authoritatively as to the exact nature of the intense congestion found on the convex surface of the meninges and on certain areas of the cortex.

In spite of very careful examination of the cerebro-spinal fluid in the two cases, we were unable to obtain unquestionable evidence of meningeal inflammation, either because there was not free communication between the perivascular sheaths and the main cavity of the arachnoid—in which event the absence of a "cup" in the fluid does not prove the absence of a reaction in the sheaths, or because *acute* uræmia does not determine any reaction.

It should be noted that pericarditis is but rarely met with in acute uræmia. It is possible that the uræmic poisons, which are of endogenous origin, are less irritating to the tissues than exogenous poisons.

As a matter of fact, the nervous lesions hitherto mentioned by writers in connection with acute uræmia do not appear to have been manifestly inflammatory. Dr. Castaigne says: "Most frequently we find generalised or circumscribed œdema, sometimes congestion of the brain and meninges, with sub-arachnoid ecchymoses, which appear to be rather the effect than the cause of the uræmic accidents."

I do not know whether genuine inflammatory lesions have been found to be the basis of the auricular troubles in renal patients. As to the retina, I am aware that in renal subjects it is often the seat of exudation, and a special renal variety of retinitis has been described, but we do not find white patches in the early stages of uræmia.

In the absence of further information, therefore, I hold that inflammatory lesions are only produced in *chronic* uræmia. The meningo-eclamptic symptoms are acute disturbances, so that we must not be surprised to find that they are not dependent on frankly inflammatory lesions.

We must, indeed, not bind ourselves to the data afforded by pathological anatomy, and, to speak frankly, the symptoms are much more dependent on the distribution than on the nature of the morbid process. This is why we must learn to think physiologically, and not anatomically, as we are so often tempted to do. I do not pretend that the nature and intensity of the lesion are devoid of importance, for it is clear that the destruction of an organ must abolish its function, but so long as a lesion is not too advanced, and is, *à la rigueur*, curable, we must pay special attention to the functional disturbance, for that, after all, constitutes the disease.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by H. Oliphant Nicholson, M.D., F.R.C.P.E., Assistant Physician to the Royal Maternity Hospital, late Obstetric Physician to the New Town Dispensary, Edinburgh. Subject: "The Prevention of Fever in the Puerperium."*

ORIGINAL PAPERS.

SOME MEDICAL ASPECTS OF SPINAL CURVATURES.

By GEORGE W. F. MACNAUGHTON, M.D., M.R.C.P., F.R.C.S.E., etc.,

Physician, Kensington General Hospital.

When briefly considering these conditions, one may affirm that kyphosis, to a greater or less degree, is present as a natural state in the two extremes of life—in the infant, before the spinal muscles acquire power to assume and maintain the upright position; and in the aged, where the anterior margins of the intervertebral discs, becoming atrophied and inelastic, permit the natural tendency of the flexor muscles to prevail over the extensors. At other times, excluding rickets and Pott's disease, this antero-posterior curvature takes place in the cervical and upper dorsal segments in osteo-arthritis, in many cases of cardiac disease, especially where pain is a feature, in lung fibrosis, and chronic bronchitis, and more decidedly when accompanied by asthma.

Lordosis of a moderate degree is more frequently met with than kyphosis, but presents less medical interest. In persons with a pronounced lumbar forward curve, the head is generally large, the figure rounded and of medium height, with an abdomen disproportionately prominent to its circumferential measurement, while the hips are broad. The disabilities attendant thereupon are backache after walking a comparatively short distance, and in swimming on the breast the lower half of the body, being deep in the water as compared with the position of the thorax, progression is hindered. Further, the legs, by being upon a still lower plane, lack force in the kick and in their return to position, and thereby lose a considerable power of propulsion.

Scoliotic changes occurring in early life and the consequent deformities present a surgical rather than a medical aspect. The converse, however, obtains in those cases attributable to occupation, postures, and debility, and which have their advent between the ages of twenty and thirty years, or even later. In these the amount of curvature apparent upon examination is no real index to the severity of the patient's distress. Just as the incidence of a rapid, though moderate, flattening of the arch of the foot in the adult is followed by numbness, heaviness, and pain in the leg upon reasonable exertion, so does slight lateral curvature present a number of indefinite and desquatous symptoms, or these occipital and vertex headaches —visceral crises, more frequently intestinal than gastric, localised and diffused neuralgias, along with temporary trophic alterations, such as swelling of the hands, form a series indicative of spinal irritation, and frequently classed as hysterical or neurasthenic. When one considers the continual effort required of the central nervous system in maintaining the tone and relative positions of muscles, and the inherent strain upon these, which, in the presence of even a slight scoliosis, sustain, at a disadvantage, the erect position of the body, then it is justifiable to conclude that many cases of neurasthenia are the consequence of lateral curvature. Moreover, a number of the cephalalgias, particularly those which arise from attempts at reading, are due to that irritability of the sensorium which accompanies curvature, and not to defects in the visual organ.

During empyema, and occasionally phthisis, scoliosis occurs as an accommodative process. There are other physical signs of medical import, however, and, of these, changes in the apices of the lungs are perhaps the most deserving of attention; thus, to whichever side the curve in the dorsal region be inclined, the scapula of that side projects backwards, and the entire shoulder passes forwards and upwards, while anteriorly, the supra and infra-clavicular areas become prominent. On the other side of the thorax the changes in configuration are exactly the opposite, and the parts above and below the clavicle become flattened and depressed. Besides these abnormalities to be observed on inspection, the breath sounds on auscultation are altered, so that in the retracted regions the breathing is harsh, vesicular, or broncho-vesicular. The percussion note is impaired; and, notwithstanding that the fremitus is but little modified, the *ensemble* is like to early consolidation of the lung, and may be readily mistaken for it.

Although not attributable in any wise to the curvature which goes with marked right or left handedness, it should be noted that many persons of middle age, who are occupied in the finer manipulative movements, such as art and penmanship, show the walls of the arteries in the arm most employed to be thickened, and the veins more prominent than those of the opposite limb. This fact should be remembered when estimating the blood pressure of the individual.

POST-OPERATIVE INTESTINAL OBSTRUCTION.

By R. J. JOHNSTONE, B.A., M.B., F.R.C.S. Eng.

Assistant Gynæcologist, Royal Victoria Hospital, Belfast; Surgeon Belfast Maternity Hospital.

Post-operative intestinal obstruction is a condition which is not very commonly met with. It occurs on an average after about 1 per cent. of abdominal operations, and is said to be more frequent after vaginal hysterectomy than after other operations. I lost one case of vaginal hysterectomy from this cause four years ago; since then I have not encountered it again until this year, when the following two examples of the condition occurred in my practice.

Case I.—Isabella McD., æt. 34, was admitted to hospital on March 30th, 1907. She had been married eleven years, had borne two children, the younger eight years ago, and had had no miscarriages. Her menstruation was regular—of the four-weekly type, lasting about three days, and not excessive. She had noticed an abdominal tumour nine years before admission, which had grown gradually larger. About five years ago she had an attack of pain over the tumour, which recurred at first about every five months, and then with rapidly decreasing intervals, until the attack coincided with each menstrual period. The pain lasted, as a rule, two or three days. She was sent into hospital by Dr. Kennedy for an attack of more severity than usual, from which she had suffered for a week before admission.

On examination, she had all the signs of a large myoma, extending up to the costal margin, with a localised dry peritonitis. Her temperature on admission was 100.4° F., and her pulse 120. After four weeks' rest in bed and expectant treatment, her temperature was normal in the morning, but still rose to 99.5 or thereabouts in the evening. Her pulse had, however, come down to 86, and I thought it right to remove the tumour.

Accordingly, on May 1st, I performed a supra-vaginal hysterectomy. I found very extensive adhesions to the omentum, and as there was a good deal of hæmorrhage from its surface after these had been separated, I tied off and removed the major part of that organ. The tumour was adherent, by its posterior aspect, to the root of the mesentery, but was separated with less trouble than might have been anticipated. The abdominal cavity was well flushed with normal saline, and left full of the fluid when the incision (a ten-inch one) was closed in three layers.

The patient's temperature that evening was 99.5, and her pulse 120. She had a morphine hypodermic to quiet her through the night. Vomiting continued during the next day, and she was given a powder containing bismuth and sodium bicarbonate without effect. I ordered her a soap-and-water enema that evening, which acted well but did not check the vomiting. On the third day after operation she was still vomiting at intervals, though her pulse had come down to 100, and her temperature to normal. Next day her pulse went up again to 110. She was given a turpentine enema which moved her slightly, but she still continued to vomit. On the fifth day after operation distension of the abdomen began to make its appearance, and as her pulse had risen to 128, and the vomit was becoming rather fæcal in appearance, I re-opened her abdomen under chloroform and ether. Distended and injected bowel at once presented itself, and, on following this up, the obstruction was seen to be caused by a recent adhesion of the gut to the omental stump, causing a kink. The intestine distal to this was quite collapsed. I freed the adhesions, and buried the omental stump in the peritoneal flaps of the abdominal wound. There was a large quantity of dark and rather foul-smelling serum in the abdominal cavity, which I washed out with plenty of saline before closing the abdominal wound in layers.

The operation was done at five in the evening, and gas could be seen passing into the collapsed portion of the gut before the wound was closed, yet fæcal vomiting continued till eight the next morning. Shortly after flatus was passed, and vomiting ceased. The bowels moved of themselves about five in the evening, twenty-four hours after operation. One or two stitch abscesses developed, otherwise convalescence, though slow, was uneventful.

My second case Sarah P., æt. 38, was also married, but had had no children and no miscarriages. She could fix no date for the time when she first noticed her tumour. The symptoms complained of were pain in both sides of the abdomen for two or three years, frequent and painful micturition, and constipation which had lasted for three weeks. For these she was sent into hospital by Dr. Hunter, of Dunmurry, who assisted me at the operation. Menstruation was four-weekly in type, lasted five days, and was profuse. She had all the signs of a large fibromyoma of the uterus, occupying practically the whole abdomen.

Her temperature rose to 99.8 on the evening of admission, but dropped to normal for the three days following, and her bowels were well moved by white mixture. I operated on August 8th—four days after admission—and removed a large myomatous uterus with a good deal of difficulty, as it was adherent over almost its whole surface to omentum and intestines. To get at the posterior adhesions I had to bisect the tumour, and even with this help the operation took two hours. The patient's condition afterwards was very bad, but by dint of repeated saline and brandy enemata and injections of adrenalin she pulled round, and went home to Dunmurry three weeks and a half after operation. Although the wound healed by first intention, her temperature rose at intervals to between 100° and 101° from the seventh day after operation to the eighteenth day, which is of interest in the light of the sequel.

She left hospital on August 30th, apparently well, though, of course, weak, and shortly after Dr. Hunter tells me that the lower end of the scar gave way and commenced to discharge thin pus. On September 23rd, almost seven weeks after operation, Dr. Hunter was summoned to see her, and found her vomiting incessantly, and with such an alarmingly bad pulse that he did not expect her to live through the night. He gave her morphia hypodermically, and, as she was a little better next morning, asked me to see her with him. I found her still vomiting, with a pulse of 140 and some distension, and, as the surroundings were not favourable for operation, recommended her removal to hospital as her only chance, which she willingly consented to.

I re-opened the abdominal wound that afternoon, after curetting the suppurating sinus which still persisted in its lower end, and found a very interesting state of affairs. Distended bowel at once presented itself, which was studded with recent tubercles. An adhesion was present between a caseous focus in the omentum and the small intestine, causing a kink. This was freed, and the caseating area removed. Several thin stringy bands running in various directions, and binding down intestine beneath them, were cut away; and, lastly, three or four coils of gut, which had become adherent to one another, and had caused considerable narrowing of the lumen of one of them, were freed from each other. A considerable amount of ascitic fluid was present. Convalescence was delayed by the skin failing to unite at the seat of the sinus, but otherwise the case went on well; the patient's pulse came down, her general condition rapidly became good, and the bowel functions were re-established the next day, and have given no trouble since. What her prospects are in the future, with an undoubted tuberculous peritonitis, is, of course, very doubtful. It will be interesting to see whether laparotomy in this case has the beneficial effect which it certainly does produce at times in this type of disease.

These cases are worth recording, as post-operative ileus is a condition which, after being for many years the bugbear of the pioneers in abdominal surgery, now receives little attention either in text-books or in journals. There is no doubt that modern aseptic technique, and better judgment in choosing the time for operations, have done much to minimise the risks; still, abdominal operations of all kinds are now so frequent that it is rather a matter of surprise that more accidents of the kind are not reported.

I would like to emphasise the insidious character of the onset of symptoms in my first case. The main, in fact, the only symptom at first was vomiting. This was continuous with the usual post-anæsthetic vomiting, which may last for twenty-four hours or even longer, especially where the operation has been prolonged and morphia has been given afterwards. The danger-signal was the continuance of the vomiting after the second day. Two motions had been procured by the administration of enemata, so that symptom was negative. The points which, to my mind, established the diagnosis were distension, most marked in the lower half of the abdomen, and the rising pulse-rate, and when these appeared I resolved to operate at once.

In the case which I referred to at the beginning of this paper, and which I lost, the symptoms were still more equivocal; recurrent attacks of vomiting were succeeded by intervals during which the bowels acted and everything seemed to be right, until when the symptoms of obstruction became declared and permanent the patient was too far gone to be saved. The obstruction in that case was a kink due to an adhesion to the wound in the vagina, and had evidently been relieved from time to time by the bowel becoming straightened out.

My last case is an exceedingly interesting one. This patient had absolutely no history of any trouble whatever, until the pains due to inflammatory changes in the tumour first appeared. At the operation there was no sign of tubercle in the peritoneum, and yet a caseous focus must have been broken down in the manipulations necessary to separate the adhesions, with the result that the infection was spread over the serous lining, and an acute tuberculous process set on foot. Such cases add another risk to abdominal surgery, but one which, I hope, the operator will not often be called on to encounter.

It is of interest to note that the abdomen in each of these cases was filled with saline before being closed, which is supposed to be a preventive against the formation of adhesions. It is more than a coincidence that each case had suffered from active adhesive peritonitis before and almost up to the date of operation; but, on the other hand, in how many similar cases does one operate without any untoward result? The "abdominal facies" which one expects in acute obstruction was conspicuously absent, both patients being rather flushed and feverish-looking. I have met with this complication on the three occasions which I have narrated, in a total of upwards of 200 abdominal sections. I hope that these cases may be of interest, and possibly of some help, to other surgeons in dealing with a condition which is, in my experience, a rather insidious, but a very real danger after operation, although, if the diagnosis be made early and the proper treatment—viz., opening the abdomen—carried out before it is too late, the results, even in the most debilitated patients, are surprisingly good.

HÆMORRHAGIC RASHES. (a)

BY GEORGE PERNET.

Assistant to Skin Department, University College Hospital, London.

Hæmorrhagic lesions of the skin, using the term hæmorrhagic in a wide sense, are usually spoken of as petechiæ, ecchymoses and vibices. In a general way petechiæ apply to small punctate spots and ecchymoses to larger ones. They are bilateral in distribution, multiple, more or less circular, but may be irregular; of a bright red tint in the early stages, varying in shade with time, much as the play of colours so grossly exhibited by a subsiding black eye. Ecchymoses may become confluent and give rise to large livid patches and areas. Again, petechiæ may pick out the pilo-sebaceous apparatus. Hæmorrhagic spots are sometimes raised, especially in erythema multiforme conditions. In vesicular and bullous eruptions, when the onslaught is severe, the contents of the vesicles and bullæ may be hæmorrhagic. A very fine hæmorrhagic stippling is also observed as a complication in long-standing eczema and psoriasis of the lower limbs, especially when varicose veins are present. With regard to vibices, they occur as streaks. In addition to the cutaneous hæmorrhages proper, subcutaneous effusions of blood may also be present.

The distinctive feature of these lesions is that their colour does not disappear on pressure, owing to extravasated blood or blood-colouring matter, thus differing from a simple inflammatory process. The first thing to do, therefore, in such cases is to pass the finger firmly over the spots, bearing in mind that in some patients they may be very tender.

The parts usually affected are the lower limbs. Next in order of frequency are the forearms and arms, and more rarely the trunk and face.

It is usual to refer to hæmorrhagic cutaneous manifestations as purpura, but I need scarcely insist on the fact that this is merely designating a symptom. The point of course is to form an opinion as to the cause, in order that treatment may be as rational as possible. I am well aware that these remarks are at this time of day commonplaces, and I would not allude to the matter were it not that diseases of the skin are sometimes apparently dealt with as if they were something apart.

In the class of case I am considering, the purpuric symptom is one that always indicates a marked, not to say serious, derangement of the organism, and it is important to be on one's guard as to possible complications, such as internal hæmorrhages. On the other hand, the skin trouble may accompany or follow visceral or orificial bleeding, or be premonitory of some general infection.

The so-called primary purpuras are really signs of intoxications and infections arising from various causes, the individual state of the tissues and of the blood playing their part of course. In approaching a case of cutaneous hæmorrhage, therefore, the importtance of taking it on its merits and of not being misled by a label is obvious. It should be dealt with on general routine lines, with special insistence on occupation, habits, food and drink, a hæmophilic history, and so forth, and bearing in mind the specific fevers. The mouth and throat should always be carefully examined, and in the case of children especially, as I shall show further on, the lungs should not be overlooked. The urine must never be neglected, as it may reveal the presence of albumin, sugar, indican, etc., or indicate renal inadequacy.

The most common condition observed is erythema purpuricum, coming into the category of erythema multiforme. The patient is often a young woman whose occupation necessitates a good deal of standing. The rash is mainly confined to the legs and thighs, where numerous spots are found which do not disappear on pressure. The older ones, for the lesions come out in crops, are level with the skin, but recent ones will be found to be elevated when more carefully examined and the finger lightly passed over them. There is frequently a history of previous attacks, recurrent at certain times of the year, a fact readily ascertained in some instances by direct examination on account of the pigmented appearances left behind. The following cases succinctly stated may be adduced as showing the diversity of causes. A domestic servant, aged 23, in whom the purpuric erythema lesions had been going on for six months, and which started after "catarrh of the liver," so she stated, a good deal of blood being passed at that time per rectum. In another woman, aged 32, the petechial and ecchymotic rash one day old came out on the legs one day after eating some crab. She had had diarrhœa for three weeks. In the case of a man, aged 42, a musician playing at times in an orchestra, the rash appeared four weeks or so after an attack of influenza. Fresh lesions came out whenever he had to sit up late. No other cause could be definitely made out. The upright or sitting posture appears to be the determining cause in some instances.

A vegetarian diet appeared to be an important factor in a girl, aged 15, who had a natural distaste for meat, and could not be persuaded to eat any. As showing the importance of examining the throat, this was well brought out in a case which commenced with reddening of the palms, and was of three days' duration. The purpuric erythema attacked the legs mainly, but was also present on the back of the hands, elbows and arms, accompanied by swelling of the knees and ankles. On looking at the throat evidence of acute tonsillitis was discovered. In another case the only apparent cause was the bad condition of the buccal cavity and the neglected condition of the teeth, with pyorrhœa alveolaris. Old syphilis and diabetes insipidus were found to exist in a man, aged 28, who had suffered from erythema purpuricum every winter for five years, with swelling of the feet and legs. Erythema purpuricum may go on to necrosis of the hæmorrhagic lesions, as exemplified in a man, aged 40, who had had a previous similar attack, brought out, he admitted, when he drank beer, not wisely but too much, no doubt. Here it may be opportunely insisted on that alcoholism is an unfavourable factor. The necrotic areas had given rise to scars, especially about the knees, that might well have been taken for old syphilitic lesions, a point of some differential diagnostic interest. A very unusual erythema purpuricum, which appeared to be due to the action of strong sunlight, was observed in a woman, aged 23, in whom the face was first affected and then the forearms. The aforementioned examples will suffice to bring out the point I desired to insist on, viz., the divers causes leading to one and the same symptom, a phenomenon of importance, I may add, in cutaneous pathology. The reverse of this is the fact that various skin manifestations or reactions may be due primarily to one and the same cause.

A more severe and rare condition is the one known as peliosis or purpura rheumatica (of Schönlein), which is here in its place after discussing hæmorrhagic erythema multiforme. In peliosis rheumatica the pains in the joints are marked, and they may be preceded or followed by the cutaneous hæmorrhages, especially about the joints. The patient is ill generally, and looks it. The temperature may or may not be raised, although in the latter case the hæmorrhagic manifestations and other symptoms may be just as severe. The absence of pyrexia must not mislead the observer, for it is in this morbid condition that it is of the greatest importance to bear in mind the possibility of serious internal hæmorrhages, which may prove fatal. In one case I observed death was the result of intestinal hæmorrhage.

Whether the qualification rheumatica is a correct one or not is a point that must be discussed. It is now so well known that many infections may lead to joint symptoms quite apart from rheumatism proper, as in gonorrhœa, for instance, that it behoves us not to use the term rheumatica in a loose way. All cases of so-called peliosis rheumatica are not specifically rheumatic in origin, but the fact remains, nevertheless, that hæmorrhagic rashes may occur in the course of acute rheumatism. Moreover, valvular cardiac lesions have been noted as a result apparently of peliosis rheumatica, so it is stated, in the absence of the general symptoms denoting acute rheumatism. Again, peliosis rheumatica has been associated with endocarditis, and although the latter has been shown to arise from various causes, the rheumatic infection must be kept in view. In practice too, salicylates have appeared to do good.

(a) A Paper read before the West London Medico-Chirurgical Society, 1907.

In other cases that come before one, and no doubt allied to the preceding, the rash may be much milder in degree, and yet the visceral hæmorrhages may be so severe as to endanger life and even to prove fatal. Here the gastro-intestinal symptoms dominate the scene, and are always an indication for caution, as an opinion must be formed not so much on the appearances of the skin as on other factors. I need scarcely emphasise the importance of dealing with cases on their individual merits, and of avoiding concentration of the attention on the skin alone.

Closely allied to the purpuric erythema I have described is the condition known as urticaria hæmorrhagica or purpura urticans, in which the urticarial wheals become hæmorrhagic. The cutaneous rash may be associated with urticarial manifestations involving mucous membranes, with hæmorrhages from the latter that may be copious. Internal hæmorrhages may occur in some cases without hæmorrhages in the urticarial wheals.

I must now consider another clinical condition which is not uncommon, the so-called purpura simplex, sometimes alluded to shortly as purpura. Here the lesions are not raised as in erythema hæmorrhagicum, but level with the skin. It is often a very recurrent complaint, going on for years, with intervals of freedom. The lower limbs are mainly affected, and the pigmentation left behind may be very great. In a young woman aged 29, for instance, who had suffered from the complaint for about twelve years, the legs were of a dusky sepia brown tint. It is true that she had had arsenic for some months, so that drug may have played a part in the production of the pigmentation. In this case there was a presystolic thrill and the catamenia were excessive. When she took tonics she bled from the nose.

In another case the purpura about the ankles was accompanied by swelling. The patient had been subject to epistaxis from childhood. The catamenia were more or less menorrhagic. On examining the urine I found albumen but no blood either microscopically, chemically or spectroscopically. The discs were normal, but in one fundus there was a white patch. I could adduce other cases to show that purpuric rashes are not infrequently associated with albuminuria. That is why I have insisted on the importance of always testing the urine, and I may add whether the patient be adult or child, for I have seen the association in the latter. I say association, although the albuminuria is in some cases, no doubt, the determining cause of the purpuric rash, other factors being favourable, the possibillity of both manifestations being the result of an intoxication must not be overlooked.

The typical petechial rash due to flea-bites must be mentioned here. In children it may be so generalised as to be mistaken sometimes for a purpuric eruption from within.

Purpura hæmorrhagica or morbus maculosis Werlhofii takes us on a further stage. This is a very serious condition, in which the cutaneous hæmorrhages are extensive and accompanied by marked and varied internal hæmorrhages, so much so that all the viscera and mucous membranes would require to be enumerated. Epistaxis may be a prominent feature, and careful plugging of the nasal passages become imperative. The skin hæmorrhages are very recurrent, so that when cases have gone on for some time, the integument may present a multicoloured appearance as a result of involuting and evoluting lesions. Notwithstanding the severity of the symptoms, patients, generally children, may recover, but owing to the anæmia and collapsed condition, convalescence is necessarily protracted. Fortunately the disease is uncommon. Morbus maculosis has been looked upon as a diathesis, an easy way of getting out of the difficulty, but I propose to touch further on this point when I deal with ætiology, as in my opinion the condition is not an entity, but the manifestation of a reaction of the tissues dependent on a variety of causal factors.

Severe forms of purpura have been variously described under the names of acute idiopathic purpura vel angiohæmatic typhus, primary hæmorrhagic purpura, and so forth. Mathieu classifies these under three heads: the typhoid form, the hyper-acute form, and the pseudo-rheumatic form [1]. But it is difficult to resist the impression that these attempts at watertight classifications are subjective artificial creations, useful, no doubt, yet as sign-posts not to be too implicitly relied upon. Here once more, it is of essential importance to be guided by what one can observe for one's self in the way of facts discoverable by careful examination. In addition to this, those who have been much in contact with morbid conditions can gather a good deal of preliminary knowledge as to a patient's state by the impression made on the observer.

In children, Henoch has described a fulminating form, purpura fulminans, in which large cutaneous extravasations occur suddenly and rapidly spread, so much so that in a few days a whole limb may be involved, with darker areas interspersed, as of threatening gangrene. There may be slight fever or none. The skin hæmorrhages increase, and death soon closes the scene. In the new-born cutaneous hæmorrhages may occur, purpura neonatorum, as a result apparently of the sudden changes in the circulatory apparatus brought about by separate existence.

Hæmorrhages into the skin, mainly affecting the lower limbs, occur in scurvy, which is sometimes arbitrarily alluded to either as sporadic, or again as true scurvy, an artificial distinction. An instructive case of scurvy which was under the care of Dr. Seymour Taylor in the West London Hospital, and described by him at length in the transactions of the West London Medico-Chirurgical Society, will, no doubt, be remembered by some of you [2]. In that patient, a woman, aged 51, the cutaneous hæmorrhages involved not only the legs but also the face, trunk and arms, evidence of the severity of the disease. At the end of his paper Dr. Taylor remarked that it was sometimes difficult to decide where purpura ended and scorbutus began, and notwithstanding that text-books taught that they were separate and distinct diseases, he was sometimes led to think that they were but varieties of the same blood disorder, and that the symptoms and signs might vary according to the severity of the attack. From my own observations I agree with most of the views expressed by him, and I have already called your attention to my opinion in this respect. But I do not think that the conditions referred to by him need necessarily be varieties of one and the same blood disorder. The cutaneous manifestations, varying in degree, may well be on the contrary the result of a variety of blood disorders. I have already mentioned the case of a girl with recurrent erythema purpuricum—in whom a vegetarian diet appeared to be one factor at any rate in the causation of the cutaneous hæmorrhages and account for her somewhat cachectic general condition. The more I see of these hæmorrhagic symptoms the more I am struck by the complexity of this problem of causation, a subject I shall have to touch upon when dealing with ætiology. In this place I should like to insist again on the importance of not taking diseases considered as entities too literally, especially from the point of view of treatment. What we have to deal with in the majority of the cases I am considering, is an organism with all its potentialities labouring under some intoxication or infection, a fact which will become more and more evident as we go on.

I may suitably refer here to the cutaneous hæmorrhages which arise either before, or in the course of, or after various morbid conditions.

Let us take enteric fever for instance. In the case of a boy, aged 19, a generalised petechial rash occurred sparing a triangular "bathing drawers" area, typical rose spots being present at the time. Widal's reaction was positive. Or, again, one may observe large areas of ecchymosis.

Purpura may follow diphtheria. In the case of a girl, aged 11, recorded by Goodall and Basan [3], there were cutaneous hæmorrhages about the limbs but very little on the trunk. No albuminuria. True it is that antitoxin had been injected, but Goodall did not consider that was the cause, as he had seen the same symptoms in a case before antitoxin was introduced. I have pointed out that Trousseau noted these hæmorrhages in diphtheria long ago: petechiæ, ecchymoses and epistaxis [4].

As is well known hæmorrhagic lesions may occur as part and parcel of the acute exanthemata, in variola hæmorrhagica for instance. Varicella hæmorrhagica is of very rare occurrence. In measles, hæmorrhagic foci may appear about the skin, going on to necrosis, especially where septic endocarditis is a complication. With regard to small-pox, a petechial rash is sometimes observed at the end of the first stage of the disease, that is, at the time the true eruption appears, or should do so. It is of bad prognosis. Again, cutaneous hæmorrhages may be interspersed between the papules or vesicles of the efflorescence. In this connection the finely punctate petechial rash recorded by Roger under the name of purpura minutissima metamerica [5] must be alluded to as of differential diagnostic importance. The case was that of a woman, aged 34, and the rash being accompanied by symptoms resembling those of variola, the question of the latter disease arose. The purpuric rash commenced in the groins and axillæ, and also about the joints, ultimately becoming generalised in a way that strongly suggested a spinal origin, hence the term metameric or segmental. Further observation showed the case was not one of variola, although at first the differential diagnosis from a premonitory purpuric rash appeared likely. It should be added, too, that the case had been sent to the isolation fever hospital under the diagnosis of scarlatina.

A purpura-like eruption in scarlet fever has been noted by Heubner [6] in a child, aged 1½, the whole of whose body was covered with lentil to thaler sized patches, not disappearing on pressure. Here and there the rash was more stippled. The child had not been isolated as a scarlatina case, as the condition was thought to be one of "septic" rash. Hubert Biss has given a good account of a purpura fulminans following scarlet fever [7] in a boy aged 3½, who had received 24,000 units of antitoxin under the idea the case was one of diphtheria. But Biss considered it was highly improbable that this was the cause of the widespread pin-point hæmorrhagic rash which supervened, and which was preceded and accompanied by other hæmorrhages (stomach, rectum). An abundant growth of streptococci was obtained from the tonsillar exudation. The child died thirty-six hours after the appearance of the first hæmorrhages. The kidneys were found to be transformed almost entirely into fat. I have mentioned this case at some length on account of the complexity of the factors present: scarlatina, antitoxin, streptococcal infection and useless kidneys. The condition described appeared to Biss to come into the category of the purpura fulminans of Henoch I have referred to, and it must be noted that one of the latter's two cases occurred after scarlet fever [8], as did also one of two cases related by Ström and Alexander [9], but I may point out that in Henoch's cases, and in two others he cites (Michaëlis and Charron), there were no hæmorrhages from mucous membranes and the necropsies were negative. Rice-Oxley and Cullen have also recorded similar cases.

Cutaneous hæmorrhages have also been seen as a complication of vaccination [10].

In erythema nodosum, which appears to be a disease *sui generis*, cutaneous hæmorrhages may be a complication.

As to the syphilitic infection, the condition known as syphilis hæmorrhagica neonatorum appears to have been first established as a fact by Behrend [11]. The clinical picture is made up of cutaneous and internal hæmorrhages, the latter involving various organs. But in adults hæmorrhages occurring in the skin during the early or so-called secondary period are uncommon. Piccardi has described an instructive case, with histological details, the subject being a man aged 38 [12]. Microscopically there were infiltrations of extravasated red blood corpuscles. In another case recorded by Weitz, he could not demonstrate hæmorrhage into the tissues, but only marked dilation of the small vessels, which were packed full of red corpuscles. This explained why the cutaneous lesions did not disappear on pressure [13].

Cutaneous hæmorrhages with hæmorrhagic bullæ may occur in the course of enteric fever in syphilitics under mercurial treatment. In a case of this kind under Robin, enteric supervened in a woman aged 25, whilst under energetic mercurial treatment for early syphilis, death closing the scene soon after the appearance of skin hæmorrhages. Duhot observed a man in whom enteric developed a month and a half after a course of mercury. Towards the end of life petechiæ occurred followed by ecchymoses and hæmorrhagic bullæ [14].

In addition to the infectious morbid conditions I have enumerated, purpuric rashes have been observed in connection with many others, such as typhus, cholera, puerperal fever, malaria, and so forth. Petechial and purpuric spots are apt to appear in epidemic cerebrospinal meningitis or spotted fever. In this disease, as you well know, the diplococcus meningitidis intracellularis is found in the cerebrospinal fluid, but I desire to allude to it mainly in connection with the important part supposed to be played by the spinal apparatus in toxic erythematous and hæmorrhagic rashes, a point I have called attention to when speaking of Roger's metameric purpura minutissima case.

Various micro-organisms have been found in purpuric eruptions. I have dwelt on some already. In the list are found streptococci and pneumococci, less frequently, the staphylococcus, bacillus anthracis, bacillus pyocyaneus and others. With regard to this point I propose to deal with it further under ætiology. I should like to say at once, however, that saprophytic micro-organisms may find their way into the blood after death, and also no doubt during life, so that their presence does not conclusively prove in certain circumstances that they are the cause of the hæmorrhages.

Again, cutaneous hæmorrhages occur in cachectic states, such as those which follow in the train of cancer, sarcoma, pernicious anæmia, etc.; also in various visceral diseases, especially of the liver and spleen [19]. In this connection may be mentioned the purpura senilis described by one of the fathers of English dermatology, Bateman, a condition observed in the aged.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

A Case of Congenital Syphilitic Osteo-Periostitis of the Femur of an Infant.

By J. B. Legg, M.S., F.R.C.S.

A male infant, 5 weeks old, was brought to the hospital with a swelling in the lower part of the left thigh. It had been noticed on the previous day whilst the child was being washed. The child was said to be rather more fretful than usual. There was no history of injury either at his birth—the presentation was a vertex and the labour was easy—or since. The mother had had one miscarriage and one child, who died soon after birth. There was no other definite syphilitic history. This baby was a rather poorly nourished child, but appeared otherwise healthy. There was no rash, no condylomata, and he did not snuffle. At the lower part of the left thigh, involving the whole circumference of the shaft of the femur, there was a uniform, smooth, hard swelling, with shelving edges, at the upper end. The skin and subcutaneous tissue were unaffected. The swelling was apparently tender, and it reached half-way up the shaft a little further on the inner side, where it was more prominent. The knee was kept in a flexed position; the infant did not move the leg, and attempts to flex or extend the knee caused the child to cry a good deal. If he was left alone, he lay quietly and was not fretful. The knee joint appeared to be unaffected. The temperature was 99.6°. All the other bones appeared to be healthy. The diagnosis, Mr. Legg said, lay between some form of inflammatory swelling and a new growth. An infant of this age was very unlikely to be the subject of a new growth: inflammatory swellings were not uncommon, and therefore until it had been proved not to be inflammatory, the question of new growth need not be further discussed. The characters of the tumour were in favour of it having been present much longer than the mother had observed. If it was an acute inflammatory swelling of the bone, and had reached the size of the present tumour, the tenderness would have been much greater, there would have been redness of the skin and œdema of the subcutaneous tissue, a greater rise in temperature, and the child would be very ill. All these signs were absent. Moreover, a leucocyte count showed only 8,200 per c.mm. For these reasons an acute infective process could be excluded. A spontaneous subperiosteal hæmorrhage was a possibility, but the child was not anæmic, and its gums were healthy. There remained practically three things, (a) a fracture, (b) tuberculous periostitis, (c) osteo-periostitis due to congenital syphilis. As regards a fracture there was no normal mobility and no suspicion of crepitus, and no history of injury at or since birth. A skiagram would be of value in excluding such injury. The diagnosis really lay between tuberculous and syphilitic osteo-periostitis. Tubercle in an infant of this age was rare in the bones: congenital syphilis was not rare, and affected the ends of the long bones, specially the humerus and femur leading to the condition known as "pseudo-paralysis," in which the joint is not moved on account of the pain, but when the pain disappears and the bone condition recovers, the paralysis also disappears. This child at present showed no other sign of congenital syphilis. Therefore, one would have to try the effect of treatment to confirm or disprove the diagnosis. It was important to remember that congenital syphilis showed itself in many ways, and there was not always present the whole picture of the disease. Unguentum hydrargyri was ordered to be rubbed in to the abdominal or chest walls, at first once and then twice daily. A very important element was that the child should be kept warm and well fed.

The child was admitted as an in-patient. A skiagram did not show the presence of a fracture. In the course of the next three weeks, under the above treatment, the swelling almost completely disappeared, the general health being much improved at the same time.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

Encephalocele.—Mr. Peyton Beale operated on a child, æt. about five months, who had been admitted under Dr. Still with a large soft tumour, somewhat larger than the child's head, projecting from the occipital region, about two inches below the occipital protuberance. The tumour was soft in consistency, and became larger when the child cried. Its point of attachment to the skull was about two and a half inches in diameter, and on carefully examining the occipital bone with the fingers it was clear that the tumour issued through a foramen of about an inch and a half in diameter in the occipital bone. The child was fairly well nourished, but for the last few days had been taking food badly, so it was determined to make an attempt to remove the tumour. After the usual preparation, a vertical incision was made straight over the mass, which was then seen to be an enormously distended ventricle covered with cerebral and cerebellar substance. A strong ligature was rapidly applied round the pedicle of the tumour, and the latter cut off. It was then seen that it was an expansion of both lateral ventricles, but it was not clear exactly what part was beneath the cerebellar substance. The stump was then ligatured in three or four smaller pieces, and the redundant skin having been removed with scissors the edges were sutured vertically. The whole operation lasted only a very few minutes, and the child appeared none the worse for it, indeed it took nourishment better during the next week. It then developed some bronchitis, and died suddenly about a fortnight after the operation. Mr. Beale remarked that these cases when they were operated upon usually died very soon from shock; he believed, however, that this could be avoided if the operation were done quickly. In this particular case there was no reason to suppose that the child died as the result of the operation, and had the bronchitis not supervened it would have been very interesting to observe to what extent the child was deficient as regards general and special sensation and motion as the result of the loss of so large an amount of cortical brain substance. As far as could be determined in this child there was no impairment whatever with reference to sensation and motion, at any rate as far as its age rendered it possible to carry out an examination on these points. He said one of the reasons for operation was the rapid increase in size of the tumour, which could not be kept in check by tapping.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

A Case of Recurrent Intestinal Obstruction.—Mr. Newbdlt operated upon a woman, æt. 66, who had previously been subjected to three abdominal sections for intestinal obstruction. The first operation was done for a large umbilical hernia fifteen years previously. The second nine years afterwards for a recurrence of the hernia with obstruction, and the third five years ago for obstruction due to matting and binding down of the intestines in the hernial sac. On admission she had a feeble pulse counting 96 to the minute, was vomiting constantly, and complained of intense colic pain. There was a large umbilical hernia, and palpitation caused the intestines to contract, giving rise to an intense colicky. Flatus was passing. From a previous knowledge of her condition it was probable that there was again a matting together of coils of intestine, giving rise to a partial but not complete obstruction. A long median incision was made, and the hernial sac laid open; coils of small intestine were found adherent to the sac and to one another. They were carefully separated from the walls of the sac, but during this process the wall of the gut was denuded of peritoneum in several places, and bleeding points had to be secured. When this separation was complete the gut was returned into the abdomen and the redundant sac excised. As the patient's condition remained good the coils of intestine were withdrawn loop by loop from the abdomen, and separated from one another. Each coil was then taken, and the denuded surface sewn over wherever it was possible to do so without narrowly constricting the lumen of the bowel. Saline was poured into the abdomen and the wound closed in the ordinary way. With the help of salines and strychnine the patient rallied well, and her bowels acted freely two days after operation. No morphia was given; her colic disappeared, and she went home three weeks after this her fourth operation eating well and feeling quite comfortable. Mr. Newbolt remarked that the four operations had all been performed in the Southern Hospital, the first by Mr. Robert Jones, and the last three by himself. Of these the second and third had to be performed hastily as the obstruction was complete and the intestines were distended. At this the last operation there was not much distension, but the vomiting and intense colic were the chief symptoms complained of. Resection of the adherent coils was out of the question, as too much bowel was involved, and the patient's condition did not justify so severe a procedure. Entero-anestomosis would have shut off a large portion of the small intestine. The patient, once a stout woman, had grown thin from malnutrition, due to her inability to take solid food. He hoped that the repair of the denuded intestine would relieve her symptoms in the future.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Obstetrical and Gynæcological Section.

Inaugural Meeting of this Section, held October 10th, 1907,

The President, Dr. Herbert Spencer, in the Chair.

Dr. **Amand Routh** reported a case of Cæsarean Hysterectomy for Atresia vaginæ. The patient consulted him at Charing Cross Hospital in March, 1906, a fortnight after delivery, for incontinence of urine. He then found that the anterior portions of the vaginal and supra-vaginal cervix had been torn away with the roof of the vagina and base of the bladder. He successfully repaired the bladder injury, and in three months' time the woman became again pregnant. She again came to the hospital in July this year, being then actually in labour. Finding that there was much vaginal atresia, and that if labour proceeded, further irremediable injury would be caused to the bladder, Dr. Routh removed the child by Cæsarean section, and the uterus by sub-total hysterectomy. Both mother and child recovered without further incidents. Dr. Routh advocated Cæsarean Hysterectomy in all such cases, and gave a table of 30 similar cases in which it had been performed, with a mortality of 20 per cent. In the 11 cases where the stump was treated by the intra-peritoneal method all the mothers recovered.

The **President** said he agreed with the author that the extensive cicatrization involving the bladder furnished a clear indication for Cæsarean section, to be followed by hysterectomy. He had seen very extensive vaginal cicatrices yield to the pressure of the head in natural delivery, but in Dr. Routh's case this would have entailed great risk of injury to the bladder. He would prefer total hysterectomy, if practicable, to supra-vaginal hysterectomy, on account of the free drainage which it afforded.

Dr. **Tate** read a short communication on a case of Œdematous Fibroma of the Pelvis. The patient was a married woman, æt. 39, who had had five children. Since the last confinement, six years ago, she had noticed enlargement of the abdomen. On admission into St. Thomas's Hospital the lower part of the abdomen was found to be occupied by a very ill-defined swelling. To the left of it the uterus could be made out the size of a duck's egg. Abdominal section was performed, and the tumour was found to consist of a large flattened œdematous mass, covered with peritoneum, and embedded in the pelvis. After securing many large vessels the tumour was removed by enucleation. The cavity thus left was packed with gauze, and the uterus then removed. The ends of the gauze plugs were brought out through the vagina, and the peritoneum brought together so as to cover up the large cavity in the pelvis. The patient had two attacks of secondary hæmorrhage, and subsequently some sloughing of the walls of the cavity occurred, but she ultimately made a good recovery. Dr. Tate found it difficult to say in what structures the tumour originated, but it certainly had no connection with the uterus. Mr. Alban Doran asked if the fibroid removed chiefly occupied the mesosalpinx or mesometrium, the portion of the broad ligament below the level of the ovary. In Mr. Doran's own case, published in the 41st volume of the "Transactions of the Obstetrical Society of London," the bulky tumour lay between the folds of the mesometrium without opening up the mesosalpinx, so that the Fallopian tubes and ovaries lay free on the upper surface of the tumour. When removing a fibroid by enucleation from the mesometrium the surgeon must remember that the ureter may run above it, though as a rule it runs below the tumour, in which case it may be firmly adherent to the lower surface of the new growth.

Prof. **W. E. Dixon** and Dr. **Frank E. Taylor** gave an Epidiascopic Demonstration on the Physiological Action of the Placenta. They set forth the results of an investigation in which they are engaged into the physiological effects which result from the intravenous injection of placental extracts into cats, rabbits, and dogs. The extracts were made by mincing fresh normal human placentæ, extracting with absolute alcohol, evaporating to dryness, and taking up the residue in saline solution. A series of tracings showing the results they obtained were projected on to the screen by means of the Epidiascope, and the effects of intravenous injection of placental extract on the circulation, the intestinal volume and movement, and on the uterus were demonstrated. There was a striking rise of blood pressure, following a preliminary fall, on injection, which was chiefly due to constriction of the peripheral arterioles. The general effect on the circulation was very similar to that produced by adrenalin, but differed from this in three ways: (1) A less rapid rise of blood pressure; (2) a more prolonged rise, and (3) a less marked cardiac effect. Intestinal volume was decreased, and its movements were inhibited. In the uterus the results differed in the pregnant and non-pregnant condition. In the pregnant uterus there was an increased tonus of the uterine musculature, together with a well-marked increase in its rhythmic contractility. They concluded that the placenta produces a chemical substance, which develops with the ripening of the placenta, the liberation of which, by contracting the uterus and the vessels, may induce the onset of normal labour.

The **President** thanked the authors for the interesting and valuable demonstration they had given, and he hoped that many more papers dealing with experimental work would be read before the Section. He asked whether the authors' results tallied with those of Acconci, who had written somewhat extensively on the subject of placental extracts. Acconci's work, "Researches on the formation of the placentine from placental extracts," published in 1906, had just come into his hands, so that he had not had time to master its contents. He thought the authors, in "suggesting a tentative hypothesis," were wisely cautious in drawing conclusions from their experiments.

Dr. **Macnaughton-Jones** said that watching the results of the experiments on blood pressure, and seeing that the increase appeared to be greater than that of adrenalin, placentine would probably prove a valuable physiological agent for administration previous to anæsthetization in serious abdominal operations, the more so now that the scopolamine, morphia, and chloroform method was frequently adopted. Since he (Dr. Macnaughton-Jones) had seen Prof. Schägers' paper and Mr. Scharlieb's experiments conducted in Edinburgh some few years since, he had always used strychnine and atropine for the same object. This, of course, was a collateral issue arisng out of the paper.

Dr. **Amand Routh** alluded to his case of "Parturition during Paraplegia" (published in 1897 in the "Obstetrical Society's Transactions," Vol. xxxix.), where the spinal cord has been destroyed by injury in the Dorsal Region five months previously. Dr. F. W. Mott and he had suggested that labour was, partly at all events, induced by the metabolism of the pregnant uterus. That case clearly proved that lactation, which was normal, could not have been induced by reflex nervous action, for the spinal cord was destroyed between the nerves going to breasts and uterus, and Dr. Routh then pointed to a bio-chemical cause arising in the uterus as being the probable exciting cause, acting through the blood. Had the authors experimented in this direction by noting the effect of the injection of placental extract upon mammary gland activity? He agreed with the authors that perverted metabolism might produce an autotoxæmia, which might cause albuminuria, acute yellow atrophy of liver, insanity and hyperemesis gravidarum.

Dr. **W. S. A. Griffith** said that the thanks of the Section were due to the authors for the paper, for the facts which they had brought forward were the result of laborious research. He could not however accept the chief conclusion which they had drawn from these facts, for which there appeared to be no evidence whatever, viz., that a substance contained in the placenta, though ascertained to increase uterine contraction, was the cause of labour either premature or full time. The question of the nature of the labour pains, as distinguished from the contractions which are known to occur throughout the active sexual life of a woman, and are so obvious during the course of pregnancy, was too large a one to attempt to discuss on that occasion. It appeared to him that the contractions of pregnancy are comparable to the colicky pains of contraction of the bowel unrelieved, and that the essential difference in each case consists rather in relaxation of the orifice than of a new form of contraction. There are many agents which increase uterine contraction, but which are almost useless for the indication of labour.

Dr. **C. Nepean Longridge** asked Dr. Taylor if the induction of labour was a long process in the case of induction at thirty-six weeks, in which he found the placental extract was very active. He mentioned that he had found a definite and progressive rise of blood pressure in a moderate number of primigravidæ during the latter months of pregnancy. He also referred to the theory of Dr. Blair Bell that labour was brought about by the accumulation of calcium in the blood. But since calcium was practically insoluble in alcohol it could not be a constituent of the extracts which Dr. Taylor had used in his experiments. One could not however deny that calcium salts had anything to do with the matter, because there are so many examples in which vital activity depends on the interaction of organic and inorganic substances in the body.

The following specimens were shown:—

(1) Chorion epitheliome of the uterus with metastasis in the vagina lungs, liver, and brain, by Dr. T. W. Eden.

(2) An instrument, by Dr. R. Wise.

(3) A pregnant uterus with fibroids, by Mr. J. Bland-Sutton.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting Held at Liverpool, Oct. 18th, 1907.

Dr. E. O. **Croft** (Leeds), President, in the chair.

INTRALIGAMENTARY BLADDER.

Dr. **W. E. Fothergill** (Manchester) mentioned the case of a single lady, æt. 28, who complained of a bladder trouble dating from puberty. For about five years micturition was necessary every hour or so to relieve intense pain in the left iliac region. None of the usual causes of bladder irritability could be found. The uterus could not be retroverted and appeared to be attached to the back of the bladder, and to dig into it as soon as two or three ounces of urine had accumulated. The abdomen was opened, and it was seen that the utero-vesical pouch was practically absent, the bladder with the small anteflexed uterus lying between the layers of the broad ligaments. The peritoneum over the fundus of the bladder was incised and the organ separated from the uterus. The peritoneum was united from side to side, so that the line of suture was antero-posterior, a utero-vesical pouch being thus formed. The fundus uteri was fastened to the peritoneum in the lower angle of the abdominal wound, to keep the uterus from pressing on the bladder. The patient a year after the operation had greatly improved in health, and had lost the pain which previously accompanied the distension of the bladder. The organ, however, was still irritable at times. Menstruation, which previously was rare and scanty, was now regular and profuse, and the uterus had gained in size and tone since it was set free from the bladder.

POST-CLIMACTERIC HÆMORRHAGE.

Dr. **Archibald Donald** (Manchester) communicated a case of unusual post-climacteric hæmorrhage occurring in a woman aged 66 years, who had one child 38 years ago. Menstruation, which began at 13 years of age, was normal and regular up to age 39, *i.e.*, 27 years ago. For 16 years there was no discharge of any kind, then irregular hæmorrhage began at variable intervals. The flow would last from two to ten days, and was not attended by any pain. The patient was markedly anæmic, and the face presented a striking appearance, being of a lemon-yellow tinge. The pulse was 90 per minute, and there was a diffuse præcordial pulsation. Bi-manually the uterus was the size of a 3 months' pregnancy. Vaginal hysterectomy was performed on May 18th, 1907, and the recovery was uneventful. On opening the enlarged uterus, its cavity contained a growth apparently originating in the endometrium, but invading the musculature. Microscopically, cylindrical down-growths of epithelial-like cells invaded the muscular wall. Professor Lorraine Smith pronounced it to be an endothelioma, probably originating in the lymph spaces of the endometrium, or body of the uterus.

A paper on the

PATHOLOGY OF SOLID OVARIAN TUMOURS

was read by Dr. Briggs and Dr. T. E. Walker. In the hospital and private practice of the former during 20⅓rd years 488 ovarian new growths were removed by operation. They were arranged in two groups, the cystic group of 439 including 284 adenocystomata, 44 dermoids, 36 broad ligamentcysts, 24 papillomata, 50 carcinomata, 1 perithelioma (sarcoma),

And the solid group of 49, including 31 ovarian fibromata, 3 fibromata of the ovarian ligament, 3 adenomata, 1 surface papilloma, 8 solid carcinomata, 1 solid teratoma (myxo-chondro-sarcoma), 1 cellular spleen-like tumour.

In the cystic group Dr. Walker, during a recent research, had found 50 ovarian carcinomata and 1 ovarian sarcoma (perithelioma). The rarity of cystic sarcoma was alluded to, and compared with the statistics of Veit and Martin, and with the general statements found in text-books. The paper was otherwise exclusively confined to the solid tumour group. Thirty-one fibromata in 488 indicate the occurrence of these tumours in 6.4 per cent.; the common text-book statement is 2 per cent. The wide range of structure observable amongst these tumours, from the structureless, or almost structureless, calcified fibroma to the highly cellular new growth was pointed out, and especially in reference to the latter a brain-like tumour and a spleen-like tumour, each of large size, were specially dealt with. The former consisted of round cells, and looked suspiciously sarcomatous when removed in March, 1897, from a girl aged 15½; this patient is now alive and in vigorous health at the age of 26; the spleen-like tumour as the after-history of the patient attested, was also innocent. The former was included in the fibromata, but the latter contained so little tissue apparently fibromatous that it was placed in a separate table, under its own briefly descriptive heading of a cellular, vascular spleen-like tumour. These features, however, were exceptional in the structure of ovarian fibromata. The common fibromatous tumours in the series consisted of spindle and round cells, embedded in a fully formed fibrous interlacement in varying proportions.

The position of the ovarian fibroma amongst solid ovarian tumours was now well estblished, and was no small tribute to the work of Leopold, published in 1874.

The fibromata included in the paper were arranged under the accepted forms of ovarian fibromata, 15 diffuse, 9 circumscribed, and 7 pedunculated. The diffuse, the most numerous, was bilateral in 2 cases, and in 7 instances the patient was beyond the menopause. Of the total the menstruation was absent in 2 diffuse and in 1 circumscribed; otherwise it was regular in 4 diffuse, 3 circumscribed, and 4 pedunculated; irregular in 1 circumscribed, diminished, in 1 diffuse. Pregnancy, in 2 cases, both circumscribed, was undisturbed by the operation. The pedicles were twisted in 1 diffuse, 1 circumscribed, and 1 pedunculated. Ascites was recorded as present in 13, absent in 18. It was least frequent with the circumscribed tumour, being present in 2, absent in 7; with the diffuse form, absent in 8, present in 7; with the pedunculated, present in 3, absent in 4. Its ætiology was considered. The fibromata of the ovarian ligament and the valuable work of Doran in this connection was alluded to.

A solid teratoma, a rare surface papilloma, and a round-celled sarcoma were each described and illustrated.

The rest of the paper consisted of a report by Dr. Walker on the solid adenomata, of which there were 3 cases, and on the solid carcinomata, of which there were 8 cases, 7 bilateral, and 1 unilateral. Of the 7 bilateral, 6 were definitely secondary, 2 to primary scirrhus of the breast, and 4 to growths in the large bowel. In the 7th case, in a woman aged 48, the primary growth was unknown, consequently it was excluded. Six-sevenths of the evidence was in support of Bland-Sutton's conclusions, that solid bilateral carcinomata are secondary.

The case of unilateral carcinoma was described.

The secondary tumours above referred to, reproduced the structure of the primary growths—scirrhus carcinoma, colloid carcinoma, and adeno-carcinoma.

OPTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

FIRST MEETING OF THE SESSION, HELD ON THURSDAY, OCTOBER 17TH, 1907.

The President, Mr. R. MARCUS GUNN, F.R.C.S., in the Chair.

THE PRESIDENT'S INTRODUCTORY ADDRESS.

MR. GUNN first tendered his warm thanks to the Society for the honour implied in his election to the presidential chair, and assured the members that he yielded to none in feelings of loyalty to the Society, whose interests he would do his best to serve. The first portion of the address was devoted to a review of the history of the Society, dating from the issue of a circular letter in February, 1880. He referred to the most important contributions to the Transactions, under various headings—physiological, surgical, clinical, pathological, etc.

Passing on to the future, he said an exact knowledge of the ætiology of affections of the cornea, iris, and choroid was much wanted, while they awaited an explanation of recurrent retinal hæmorrhages in eyes otherwise seemingly sound, in persons whose general health was not manifestly at fault. If a diminished coagulability of the blood were found to be present, and that was kept at bay, it was reasonable to expect that the recurrence due to that cause would be checked; but such treatment had been disappointing. Opacities in the lens occasionally presented forms which did not seem inexplicable at all by our knowledge of its anatomy or its nutrition. Could those be accounted for?

Prognosis was a very important matter to the patient, yet it was often uncertain, and must continue so. Yet if the ophthalmic surgeon knew a little more of the true nature of the different diseases which he had to treat, his knowledge of their course and duration would be materially increased. In the past few years a great advance had been made as to the nature of infective agents, and the ways in which the body attempted to free itself from invasion. There was the whole army of bacterial poisons, with their anti-bodies, and ophthalmic surgeons must know sufficient to be able to intelligently follow the reason involved in serum and vaccine therapy. If it was useful in their specialty, they must inquire when and how far, and how it should be employed. With regard to medicinal treatments, he hoped they would keep their armamentarium as small as possible without the sacrifice of efficiency. Too many drugs were a weariness of the flesh, both to him who gave and he who took.

He thought the Society might well revert to more frequent committees and discussions, as in the earlier history of the Society. He referred to the large number of card specimens now shown before the Society, many of them of great interest and importance, but members did not seem able to take full advantage of them, and their very number was the cause of that inability, for they could not see all, if, indeed, they could see any, satisfactorily in half an hour in a crowded room. The institution of clinical evenings was quite an advance, but much still remained to be done. It would be well to have standing committees for men interested in special lines of work, whose duty it would be to report upon any case when the member showing it approved. Of such committee the exhibitor would be a member for the time being.

Mr. J. B. LAWFORD read a paper entitled

A CASE OF TUMOUR OF THE OPTIC NERVE.

The patient was a female, æt. 38, single, who came under observation in June, 1906. The eyelids on the left side were puffy and slightly red; there was a moderate degree of proptosis, the displacement being almost directly forwards. The movements of the eyeball upwards and outwards were restricted, rotation downwards and inwards full. No œdema, and but slight vascularity of the conjunctiva. No tenderness on pressure; nothing abnormal in the orbit; no pain, but some discomfort. Vision was reduced to perception of light. The media were clear, the optic papillæ ill-defined and pale, and the retinal veins tortuous. No hæmorrhage or disease of the choroid. The family history was good, the patient was a healthy, robust woman, and tubercular and syphilitic disease could be reasonably excluded. There was no history of injury. Something amiss was noticed in the left eye four years previously, and in April of that year she consulted Mr. Wherry, of Cambridge, who recorded the vision on that date as follows: R. 6/6; L. 6/18, but with correction of hypertrophic astigmatism, 6/9 partly. The patient was seen by another ophthalmic surgeon during 1903-4, and was under treatment by drugs for some months, but there was no improvement in the symptoms. The diagnosis made in 1906 was (?) tumour of optic nerve sheath, (?) osteoma of orbit.

Treatment by iodide of potassium was advised, and was carried out for some weeks, but without benefit. In July, 1907, there was a slight but noticeable alteration, the proptosis had increased, the movements of the globe were much restricted in all directions, the pupil was inactive to light, and there was no perception of light. The patient could not state how long the blindness had existed. No hæmorrhages could be distinguished, the retinal veins were tortuous, there was no tenderness, no tumour could be felt, or deep pulsation detected by the finger. The proptosis could not be reduced by pressure. There was no severe pain. The general health did not appear to be prejudiced by the orbital disease. Operation was advised.

Three days later the patient was seen by Sir John Tweedy, who thought it was either osteoma of the orbital wall or tumour of the optic nerve, probably the latter. In June, 1907, the eyeball and tumour were removed. The tumour extended from the back of the eyeball to the apex of the orbit, and the nerve was divided as close to the optic foramen as possible. There was extensive hæmorrhage into the orbital tissue; the swelling gradually subsided, and she left the nursing home a fortnight after the operation. Fifteen similar cases had already been recorded, which was in contrast to the number of cases of primary intradural tumour of the optic nerve, which numbered 102 up to 1901. The age of his own patient was above the average.

The microscopical characters of the growth were described and demonstrated by Mr. George Coats.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, October 4th, 1907.

The President, Mr. Richard Lake, F.R.C.S., in the chair.

Mr. Lake read his Presidential Address on "Some Reflections on the Relationship of the more important points of Diseases of the Ear and Nose and General Medicine."

He dwelt upon points chosen to illustrate more particularly the effects of various constitutional complaints upon the ear and nose; and the effects upon the general state of the body when the ear and nose are affected.

LIVERPOOL MEDICAL INSTITUTION.

First (Inaugural) Meeting of the Session, Held Thursday, October 10th.

The President, Mr. F. T. Paul, F.R.C.S., in the Chair.

The President delivered an address on Abdominal Surgery.

On the proposal of Mr. Edgar A. Browne, seconded by Mr. Rushton Parker, the President was accorded a most hearty vote of thanks.

Subsequently the President entertained 150 members to supper and a smoking concert.

Dr. Hope reported to the Liverpool Health Committee on October 9th that the death-rate in the city for the past week was 18.1, as compared with 22.0 for the corresponding period last year. There were in the hospitals 624 cases, including 402 of scarlet fever, 12 of typhus, 51 of typhoid fever, 12 of measles, 53 of diphtheria, and 12 of phthisis. Mr. Jacob brought before the committee an offer made by the Hon. Nathan Strauss of New York, of a pasteuring plant for the preparation of milk for infants, and Dr. Hope having reported favourably on the matter, the committee, o nthe motion of Mr. Shelmerdine, seconded by Mr. Jacob, resolved to accept the offer, with thanks.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 20th, 1907.

Origin and Treatment of Cancer of the Stomach.

Carcinoma of the stomach sets in, according to Prof. Robin, in an insidious manner. It begins by anorexia, with a pronounced dislike for certain kinds of food, as meat and wine. The patient is seized with vomiting, which is one of the usual signs of carcinoma, and is caused by the seat of the neoplasm at the orifices, trouble in the gastric secretion, and the presence of the tumour itself.

The vomiting presents several varieties, the most characteristic is that observed in the morning fasting, or during the day, preceded or accompanied by a nauseous feeling, and constituted by watery liquids produced without effort as a simple regurgitation; it is the cancer liquid. At other times food is vomited several hours after meals, and procures great relief to the patient. The matter vomited has a sour and putrid odour. Hydrochloric acid is wanting, but acids in process of fermentation are abundant, due to the microbian organisms which are in constant development.

At a later stage of the disease black vomiting—colour of coffee grounds—sets in, and is due to the blood derived from erosion of the vessels of the morbid tumour.

Hematemesis, properly called, are rare in gastric cancer; they belong rather to ulcer of the stomach.

An important symptom is pain. It is very common, but has not the acute character of ulcer. The patients complain rather of a sensation of weight, with a few lancinating pains over the seat of the tumour, which is sensitive to pressure. This painful sensation does not entirely cease in the intervals of meals. It is not, however, immediately exasperated by the ingestion of food as in ulcer, but increases slowly during the digestion, when it is frequently complicated with pyrosis.

Constipation is the rule; diarrhœa is only observed in the advanced period of the disease. Palpation of the stomach reveals the seat of the neoplasm; when the organ is not distended the pylorus may be considered intact.

Analysis of the chemical composition of the gastric secretion can give useful information. Some time ago the absence of free hydrochloric acid was a pathognomonic sign of cancer, but this absence was demonstrated in a large number of other maladies, while in carcinoma an excess of this acid was sometimes observed. However, this absence has a certain importance in doubtful cases.

Physical signs should not be neglected. It is not the stomach alone that should be examined, but also the condition of other organs, as the liver, the omentum, peritoneum, or the umbilicus. Divers ganglions should also be sought for, especially above the left clavicle, which, if present, constitute a counter-indication to surgical interference.

The legs are frequently the seat of œdema, and sometimes of phlegmatia alba dolens, localised chiefly in the veins of the calf of the leg.

Sometimes fever exists to a certain amount, resulting from gastric fermentation, but usually passes unperceived. At other times, on the contrary, it reaches 104°, and is due to absorption of the toxic products.

As to treatment, condurango, chlorate of soda, iodide of sodium, methylene blue, bichromate of potash, thuya, etc., enjoyed some favour, and gave temporary relief, but Prof. Robin recommends bihydrochlorate of quinine in 10-grain doses twice a day, and cacodylate of soda, while the cachectic condition might be treated with injections of glycero-phosphate of lime, 5 grains daily for 25 to 30 days.

Chelidonium, or its alkaloid, chelidonin, has been much recommended by Deiussenko, Ivanov, Kraisky, Meyer, Robinson and others. In cases of ulcer of the stomach, carcinoma, cancer of the intestine, the results obtained would seem to have been favourable and rapid; under its influence the tumour diminished, and a general improvement took place. It acts as an hypnotic, and moderates the development of the neoplasm. Chelodonin is given in pills of 2 milligrammes in progressive doses (3 to 12 daily), according to tolerance.

Although there is no curative treatment for cancer of the stomach, there is a medical treatment sufficient to prolong life, relieve suffering, and give hope to the patients. Gastro-enterostomy should be reserved when it is impossible to otherwise relieve the pain of certain cancers.

Treatment of Vomiting.

Hydrochlorate of cocain,
Hydrochlorate of morphia, } ā ā ½ gr.
Lime water, 6 oz.
A tablespoonful every hour.

Or,

Hydrochlorate of cocain, 1 gr.
Antipyrin, 30 gr.
Syrup of oranges, 6 oz.

Or,

Tincture of iodine, 1 dr.
Chloroform, 1 dr.
5 drops every half-hour up to 19 drops (pregnancy).

Or,

Tincture of iodine, 30 m.m.
Spirits of chloroform, 2 dr.
Water, 4 oz.
A tablespoonful every hour.

GERMANY.

Berlin, Oct. 20th, 1907.

At the meeting of the Society for Public Health, the subject of

Epidemic Cerebrospinal Meningitis

came up for discussion. Statistics were brought forward by Professor Flügge, who also answered the question as to how infection took place. There was no longer any doubt that the disease was caused by Weichselbaum's meningococcus. The apparently healthy were the dangerous ones. The disposition to contract the disease was mostly amongst children, and especially those with enlarged tonsils. It was the coccus carriers, who felt well and not those who were ill, that were the disseminators of the disease. The principal danger was for those in the immediate neighbourhood of the centres of infection.

It was certain that the disease was introduced into localities previously free by healthy persons coming from an infected district. Isolation was certainly necessary but not indispensably so. Disinfection did but little service. All those around a case of the disease should be looked upon as carriers of it. It was necessary that instructions should be given that intercourse with those in the neighbourhood of the disease should be carried on as cautiously as possible; that those who were healthy should receive warning in regard to those coming from infected houses for at least three weeks; that children from such houses should be kept away from school for several weeks, etc. The carriers of the bacilli should be looked after daily by the medical officers. The serums prepared by Merck and also that of Kolle, of Bern, were of value both for diagnostic and therapeutic purposes.

Hr. Bruhns, Gelsenkirchen, agreed with what had been said. The society for combating folk-diseases should erect small sanatoria in many localities, where the bacillus bearers could be examined at once.

Professor Erismann, Zürich, would isolate all the bacillus bearers, regardless of all other considerations, but would compensate them for loss of work. Hr. Czaplewsky, Cöln, drew attention to the special danger of kissing.

Geh. Obermed.—Rat Kirchner, Berlin, said there was not money enough to separate all the bacillus bearers, and there was no possibility of shutting up more than half the population. Those infected must be isolated under any circumstances. Wherever the disease appeared the State should at once send bacteriological experts, cover the country with a network of bacteriological institutions, and steadily draw the net closer. The different parishes must disinfect free of cost.

Hr. Deneke, Hamburgh, thought the time would come when an outbreak would be foretold, and the population receive timely warning.

Stabsarzt Dr. Kutscher, Berlin, thought that as the cocci did not grow outside the body there must be permanent bacillus bearers. The bacilli frequently disappeared for a time, to return again later on. In the Institute for Infective Diseases two kinds of serum were prepared and distributed gratuitously, one in the form of snuffing powder for bearers of germs, and the other for those who were ill of the disease. The serum was only active during the first three days, and must be used quite fresh.

Dr. Peerenboom, Wilhelmshafen, proposed that when an epidemic threatened all the lymphatic children who were likely to take the disease should be removed to convalescent homes in time, and detained there.

The Influence of Mineral Waters on the Digestive Tract.

The *Deutsche Med. Zeitung*, No. 76, has a reference to a paper on this subject by Dr. Pewsner. In it the writer claims that experiments on animals have shown that the mechanism of gastric secretion is identical in all particulars in the human subject and in dogs. Experiments, therefore, that have been carried out with regard to the action of mineral waters on animals with gastric fistulæ must have a certain value clinically. Mineral waters that contain carbonic acid (Seltzer and Ems) increase the gastric secretion very much. Simple service drinking water increases it moderately, Carlsbad water diminishes it, purely alkaline mineral water (Vichy) and bitter waters (Hunyadi-Janos, Friedrichshall) diminish it very much. The amount of pancreatic secretion does not run parallel with the quantity of water taken. As regards the digestive power on albumen and starch, the gastric juice secreted after taking Vichy water takes the first place. The juice secreted after taking ordinary drinking water takes the last place of all. He thinks that the importance of mineral waters in the treatment of disorders of the digestive tract should not be overestimated. Where mineral waters are made use of it is above all important that the diet should be in every way suitable.

AUSTRIA.

Vienna, Oct. 20th, 1907.

Tuberculosis.

The conference on tuberculosis has finished its deliberations for another year, without marking any epochal event. The disease is still cutting off 2.5 per thousand, or a 1-7th of those who die are tubercular according to the official reports, which would stand at a higher figure were it not limited by insurance pressure.

The Vice-President, Prof. Schrötter, greeted the members in the Grand Festesaale of the University. States, corporations, and private bodies were represented by deputies. In his remarks Schrötter hoped that this fiend would soon be arrested in its destruction, but feared it would not be overcome till the people practised hygienic principles and drove it from their midst by their own efforts.

Bienerth, Austrian Minister for the Sanitary Department, described many of the methods and institutions they had erected in Austria to reduce the number of victims dying from this disease, and praised Schrötter for his rational and scientific assistance he had given to his own department. He had still hope that these humane institutions would lead Austria to improve her hygiene and social politics.

The first paper was read by Prof. Weichselbaum on the method of infection. He reviewed the earlier notions, and said our present knowledge was still imperfect, and the method of infection attributed to two channels, inhalation and alimentation, these being supported by Calmette and Flügge.

Calmette holds that tubercle is conveyed to the system through the alimentary tract, particularly the bowel, and that dust or moisture had no share in the communication. On the other hand Flügge is as firmly convinced that his "drop" theory of the infection passing in by the lungs is the correct one.

He believes it is conveyed by the mouth in dust or moisture, and trickles down the trachea to the lung or finer bronchi. Calmette founds his opinion on animal experiments, while Flügge draws his from cases entering his own institution. Between these extremes other authors form a grand mean of the infection being taken in by both channels. Weichselbaum recorded many of his own experiments performed before the discovery of the tubercular bacillus in feeding dogs with sputum, which convinced him at the time that tubercle was not so easily taken in by the animal species by the alimentary canal as through the lung. Since that time he has somewhat modified his opinions. In the pulmonary and bronchial glands the bacilli are fewer than in the cervical and glands of the mesentery. In the latter the process is more rapid and intense in development. The earlier theories were that the pulmonary and bronchial glands were physiologically reduced, and in the older experiment with animals the anthracosis was attributed to this cause, while in the later experiments the low development in the lymphatic tissues was reduced below that of the neck and mesentery. This explanation accords with the earlier examination of the lymphocytes, which are supposed to have played an important part in fighting the tubercular bacilli; it therefore resolved itself into an imperfectly developed lymph system as opposed to the formation of lymphocytes. Notwithstanding the alimentary theory Weichselbaum is convinced that the air and the lungs still play an important part in the connection of the bacilli through the bronchial glands.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Professor Chiene's Reminiscences.—Professor Chiene opened the class of Systematic Surgery on the 16th by a retrospect of his work as a teacher. "Forty years ago," he said, "John Goodsir sent for me to his house at Wardie. I found him lying in a narrow, camp-like bed, in a narrow room, a small table at his side, and on the table Quain's 'Anatomy' and his Bible. He asked me how the students were getting on, and bade me farewell. His last words were, 'Teach the students, Dr. Chiene,' and I have taken these words as my life motto. To-day, when I celebrate my silver wedding—twenty-five years a professor—I take as my subject 'Looking Backward.'" Professor Chiene then gave a sketch of his career since graduating in 1865, and recalled how, at three o'clock one afternoon, Professor Turner asked him to give the four o'clock demonstration in anatomy. He felt a little nervous, and went into the lecture theatre, but forgot to turn up the gas on the body, and delivered the demonstration. The students were kindly fellows; they never by word or look pointed out the omission, and he only discovered it next day. From the anatomy theatre Professor Chiene took his audience to the old building on Nicholas Square, where he at one time had his systematic class. The turning-point, however, in his surgical career came in the spring of 1866, when he was introduced to Joseph Lister. From the day Lister came to Edinburgh in 1866 until he went to King's College in 1878, Professor Chiene spent daily two hours in his wards, and watched Lister at his daily work elaborating with zeal, and patience, and doggedness the imperishable system which he had been privileged to see an accomplished fact. The comparison of work in the Edinburgh Royal Infirmary in the early 'eighties and now was of interest, remarked Professor Chiene. In the first period 752 operations were performed—107.3 per annum; 24 years later 2,803 operations, or 400.5 per annum. Taking the general mortality over the two periods, the percentage of deaths was 7.2 between 1878 and 1885; 6.7 between 1899-1905. In 1882 he started the first teaching bacteriological laboratory in the United Kingdom, and when the new regulation became law in 1902 the teaching of bacteriology passed into the hands of the Professor of Pathology. After some further reminiscences of the nurses who had worked under him, and of his early personal friendships, Professor Chiene went on to say that it was the kindly, gentle people who were remembered, while the pushers—rhinocerous-hided or serpentine in their ways—were soon forgotten. He urged the students to read their Bible; he sometimes thought it would be a good thing if the Bible formed one of the subjects for the medical preliminary examination. A man who knew his Bible well was on the way of becoming a good surgeon.

Larbert Asylum.—In the evolution of asylums into "hospitals" for the insane, the female nurse has been a very important factor, and has done much to revolutionise the internal economy of such institutions. In accordance with these facts, a handsome new nurses' home has just been completed in the Stirling District Asylum, and will provide accommodation for 85 nurses. Special features have been made of the library and lecture-room, so as to enable nurses to study and get special training in mental nursing. So successful has the female nurse proved in the management of the insane, that asylum directors are now anxious to attract the best class of women. The whole atmosphere of asylums has been changed in consequence of the advent of female nurses. Excited male patients, it is found, who would fight with one of their own sex, never dream of striking a woman. As an example of the progress which has been made at the Stirling Asylum, Dr. Robertson states that for many years not a patient has been locked up in a single room in the institution either by day or night. Padded rooms have become store-rooms, and the strait-waistcoat is obsolete. The new home will shortly be formally opened by Lord Balfour of Burleigh. It has cost the directors £10,000.

Fatal Attack on an Asylum Attendant.—Daviot Asylum, a branch of the Aberdeen Royal Asylum, where harmless patients who can do agricultural work are located, was last week the scene of an unfortunate tragedy. A number of patients were engaged, under the supervision of attendants, in cutting thistles in a field. While they were returning from work, one of them was seized with a sudden impulse, and, without the slightest warning turned on one of the attendants and inflicted on him with a scythe a frightful wound in the throat, which was almost immediately fatal. The patient who committed the deed had never shown any sign of homicidal tendencies, and was of a quiet and inoffensive disposition.

BELFAST.

Derry County Infirmary.—An interesting discussion took place at the monthly meeting of the County Infirmary at Derry last week, when the resident surgeon, Dr. J. G. Cooke, made an application to be allowed to take consulting practice outside the county as well as in it. He promised to provide an efficient substitute during the time he might be absent from the infirmary. A good deal of objection was raised to the application on the ground that it would be in surgical cases that Dr. Cooke would most likely be consulted and that he would have to operate, and be absent for rather long times. The Chairman of the Board wanted to make it a condition that Dr. Cooke should pay a junior house surgeon £50 a year to spend his whole time in the infirmary, and be subject to their regulations. It was not clear whether by an efficient substitute Dr. Cooke meant some one to keep an eye on the place in his absence, or some one actually to sleep in the infirmary if he were absent for a night; some members of the Board thought that the latter should be the understanding. Eventually the original proposal was accepted, and leave granted to Dr. Cooke as asked, without special restrictions.

Royal Victoria Hospital.—The winter session opened at the Royal Victoria Hospital on Thursday, 17th, with an address by Dr. R. J. Johnston, assistant gynæcologist. In the absence of Dr. J. Walton Browne, the chair was taken by Sir William Whitla, the senior member of the staff present. Dr. Johnston gave an interesting and humorous address on the general education of the medical student, dwelling specially on the necessity for training the mind in right methods of thinking. On the motion of Sir John Byers, seconded by Professor Symington, a hearty vote of thanks was passed and conveyed to Dr. Johnston.

LETTERS TO THE EDITOR.

THE PROFESSION AND THE PUBLIC.

To the Editor of The Medical Press and Circular.

Sir,—Some of the chief items in the current issue of your admirable journal form painful reading for those who love their profession and appreciate the fine spirit that pervades the majority of its members. There is first the quotation from the Socialist children's catechism. The malignant feeling there displayed is very largely the direct product of the teaching of rabid anti-vivisectionist and anti-vaccinationist fanaticism. The former constantly holds up the profession to execration, if not as practisers of fiendish cruelty, as admirers of men who devote their lives to deliberate infliction of suffering upon helpless brutes, well knowing that useful results are more than doubtful. The teaching of Mr. Stephen Coleridge among laymen, and of Archdeacon Wilberforce, chaplain to the Speaker, among the clergy, may be cited in this connection. Your editorial note headed "Vivisection Horror" exemplifies once more the methods of fanaticism. Then the anti-vaccinationist's favourite statement is to the effect that for the sake of the paltry fees which the duty brings, the whole profession is engaged in a vile conspiracy—they even vaccinate their own children to supply colour to their hypocrisy—to disseminate a loathsome poison throughout the population. These teachings prepare a fruitful soil for the operations of fraudulent quackery, which, again, is dealt with in another of your pages. The cynical and cruel rogues who find fortune in one or other of the lines of quackery gain ready victims among simple, innocent, and suffering, and therefore confiding, people, wrought upon by the enemies of scientific medicine. Every practitioner of experience must encounter numbers of wretched patients who have left their diseases to pass into hopeless phases whilst relying upon the promises of ignorant knavery. The amount of easily preventible human suffering and misery which is being indirectly caused in this country alone by the teachings of "anti" fanatics outweighs ten thousand times the pain inflicted upon the lower animals in all the physiological laboratories throughout the entire world. In the meantime, the profession remain passive, if not apathetic, in presence of systematic libel and vilification, and make no effort even to demand or force from the State the dues justly owing to them in return for the obligations they are obliged to fulfil in obtaining what remains so far a really worthless status.

I am, Sir, yours truly,
Physiologist.

October 18th, 1907.

THE GOVERNMENT'S SCHEME FOR THE PROMOTION OF UNQUALIFIED MEDICAL PRACTICE.

To the Editor of The Medical Press and Circular.

Sir,—Dr. Moore, of Huddersfield, claims to be the true begetter of the "Notification of Births Bill" (Medical Press, October 10th), and I will not question its genesis; but I will beg of Dr. Moore to remember that we are members of a profession which claims to be free and enlightened. In our search for truth we must occasionally criticise the views of each other, and Dr. Moore must not complain if we exercise our privilege to comment on the possible effects of his Bill.

I am prepared to believe that Dr. Moore, with the aid of his two very efficient lady doctors, can have the Notification of Births Act carried out without encouraging unqualified practice; but I am firmly convinced that unqualified practice must result from its adoption in most big cities.

It is a presumption of law that a man must be held to intend the natural and proximate effects of his act, and I insist that the natural and probable effects of an Act which thrusts an unqualified nurse on a family the moment a child is born, to direct its rearing, must result in the establishment and encouragement of these unqualified persons, to the detriment of the medical practitioner and the infringement of his rights.

Regarding the discussion of the Bill generally, I think that I must complain of Dr. Moore. The views put forward in my paper which appeared in The Medical Press were given, in effect, in some comments which I made on the communication of Dr. Moore to the Douglas Public Health Congress. I may be right, or I may be wrong, but I claim the right to discuss such papers freely, for unless both sides of a question be debated, it is impossible to arrive at the truth. The Douglas newspapers made a sensational paragraph out of my observations, which I never saw or took notice of, but some of my political opponents in the Dublin Corporation wrote to Dr. Moore inquiring if the paragraph in question represented what I had said. Obviously, a sentence or two, detached from its context, is very likely to convey an erroneous impression; but, in spite of my denials, and the statements of the gentleman who presided at the section, Dr. Moore's communication to the gentlemen in question seems to have inspired them with the belief that I advocate the callous neglect of delicate infants, if not their wholesale murder.

Subject to your ruling, Mr. Editor, I submit that if a number of doctors are discussing a scientific subject in a scientific way, each should be at liberty to express himself freely; that if a lay paper, for the sake of making sensational statements, suggests that one of the speakers advocated something like child murder, and the doctor in question repudiates the insinuation, and the president of the section likewise, his colleagues should not answer his political opponents behind his back to the effect that his repudiation was not to be believed, and so encourage them to have the repudiated report placarded on the walls of the City Hall of his native town.

This is what has happened to me. The views which I expressed at Douglas or in your journal I am ready to defend, as to their truth and their wisdom, in any medical journal, or before any body of my colleagues. It does not follow that I should be called on to defend them in the Dublin Corporation or amongst my patients. It was not a lay sermon to the laity, but a scientific discussion before a scientific audience.

There must be an end of free discussion amongst medical men if one of them is at liberty to convey to lay outsiders a garbled account of the statements of another. Thus, I happen to be a Fellow of the Royal Society of Medicine. If I should chance to take part in a discussion on any subject, if my opinions are not those usually held, and if some lay paper makes a paragraph imputing views to me which I repudiate, is the person whose paper is criticised to communicate with my adversaries in the Corporation of which I happen to be a member, and give them an opportunity of perhaps blasting my career for ever?

I suggest that the unwritten law of the profession requires that when medical men have a scientific discussion, and when views are imputed to one of the participants which he denies, and which are calculated to do him harm, it is the duty of his medical colleagues to accept the denial, and not to communicate with outsiders who wish to impeach him on the question.

I am, Sir, yours truly,
J. C. McWalter.

October 10, 1907.

CASE OF THE LATE DR. J. P. MAGUIRE.

To the Editor of The Medical Press and Circular.

Sir,—On behalf of the widow of the late Dr. J. P. Maguire, I thank you for the assistance you have given by publishing my appeal in your columns. Appended hereto is a list of names of those who have generously subscribed, and who now have the satisfaction of knowing that their charitable and kindly action has rescued this deserving case from penury, enabled her to pay the expenses of training as a midwifery nurse, and so earn her living in the future.

I intend to close the list on the 9th prox., and as the widow has many expenses to meet I hope to receive some more subscriptions before the list is closed.

I am, Sir, yours truly,
R. B. Mahon.

Ballinrobe, co. Mayo,

SPECIAL ARTICLES.

THE DUBLIN HOSPITALS.

As our readers are aware, certain of the Dublin Hospitals, nine in number, viz., the Westmorland Lock, Dr. Steevens', the Meath, Cork Street Fever, the House of Industry, the Rotunda Lying-In, the Coombe Lying-In, the Royal Victoria Eye and Ear, and the Royal Hospital for Incurables, are in receipt of direct grants from Parliament. These grants vary in amount from £100 to the Royal Victoria Eye and Ear Hospital to £7,563 to the House of Industry Hospitals. In order to exert a general supervision over the management of these hospitals, a Board of Superintendence is in existence, which inspects them and presents an annual report to the Lord Lieutenant. The signatories to the present Report (*a*) are twelve in number, together with the Secretary. The Secretary and four of the members of the Board are medical men. The Report, as we have been accustomed to it for many years, consists of three parts:—(1) General comments on the hospitals as a group; (2) brief reports on the condition of each hospital; (3) series of tables giving information regarding each hospital as to the diseases treated, the sources of income and the channels of expenditure, the dietaries, the cost of provisions, and other such matters.

These tables, if trustworthy, are of value to all interested in hospital management, and the comparison afforded should be particularly useful to the authorities of the hospitals under review. On glancing at the tables some curious contrasts are noticed. Thus, comparing the three general hospitals as regards the average annual cost per bed for maintenance, we find that in Steevens' and the Meath the cost is £23 5s. 7d. and £21 5s. 3¾d. respectively, while in the House of Industry it is only £14 18s. 3½d. Again, comparing the two lying-in hospitals, we find that the Rotunda, with an average of 88 beds occupied, spends £6 1s. 2d. on stimulants, whereas the Coombe, with less than half the number of beds (38) spends more than twice that sum (£15 4s. 1d.). We have called attention to this contrast in previous years. Again, the drug bill at the Coombe is some twenty pounds greater than that at the larger institution; while, stranger still, the drug bill at the Royal Victoria Eye and Ear Hospital is the largest of any, though it has only an average of 71 beds occupied, against 158 at the House of Industry.

Certain of the tables, however, are hardly intelligible as they stand. Thus, from Table No. 5, p. 29, which purports to show, among other things, "the present extent of accommodation for each class of patients," it would appear that there are no beds for lying-in patients, incurable patients, or ophthalmic patients, although four of the hospitals in the list are devoted specially to these classes. Presumably, the returns have not been made, but if so, this should be stated. It is, however, on comparing the mortality as given in this table with that as given in Table No. 1, pp. 10-24, that we find the most astonishing discrepancies. The figures for the hospitals, regarding which information is given in both tables, are as follows:—

	Table I.	Table V.
Westmorland Lock	0 ..	5
Steevens'	52 ...	52
Meath	79 ...	78
Cork Street	193 ...	200
Hardwicke	63 ..	46
Whitworth	64 ...	43
Richmond	36 ...	64
Coombe "Chronic Wards" ...	0 ...	1
Royal Hospital for Incurables ...	40 ...	40

It will be seen that only in two cases do the figures tally.

Turning from the tables to the body of the Report, we find that the Board saw everything, and, behold, it was very good. Praise is lavished on everyone concerned in hospital management, and on every detail of the hospitals inspected. Nowhere is to be found—we do not say the slightest censure—but the slightest suggestion for improvement. We are quite in accord with the Board in believing that the Dublin hospitals are, on the whole, well and economically managed, and in urging that more money is sadly needed, but we can hardly regard them as perfect. As an example we may refer to the case of one hospital, on whose management we have had before now to comment adversely. The Report says:—

> "The Lock Hospital.
>
> "On inspection we found the wards and other parts of this institution thoroughly clean, well ventilated, and in excellent sanitary condition. The bedding and bed-clothes were in good condition, the floors were well scrubbed, regularity prevailed in every department, and the whole management impressed us as highly commendable. Each patient was questioned as to whether her comfort and well-being were satisfactorily attended to, and the answers without exception were in the affirmative. In the basement we were struck by the cleanliness of every corner—a condition difficult to bring about and maintain in a very old building. The method of cooking is good, and the different descriptions of food were all that they should be."

In 1903, we commented (Medical Press and Circular, July 8th, 1903) on the strained relations which existed at the time between the Lady Superintendent and the nursing staff, owing to which three of the four staff nurses resigned. We understand that these relations have not improved since that time, and that whereas at the date of the recent inspection by the Board of Superintendence there were three staff nurses in the hospital, there is now only one. Moreover, this remaining nurse is the maternity nurse, who should not be supposed to concern herself with other than maternity duties. From the Report it would not appear as if there were any maternity cases in the hospital, whereas we understand that there is an average of some five-and-twenty in the year. We conceive that it is the duty of the Board of Superintendence to inquire into and comment on such matters as these. It is not through ignorance of them, however, that the Board has kept silence. The affairs of the hospital were brought before the Board by one of its members, who expressed strong dissent from the paragraph we have quoted. In spite of his dissent, his signature is attached to the Report, though we understand he has since sent his resignation to the Lord-Lieutenant as a protest against such treatment.

The Board of Superintendence has a serious duty to perform to the hospitals of Dublin and the public.

(*a*) "Forty-Ninth Annual Report of the Board of Superintendence of the Dublin Hospitals, with Appendices, for the Year 1906-1907." Dublin: H.M. Stationery Office. 1907.

It is its duty to bring an intelligent and independent criticism to bear on the management of these institutions. Strictures should be made where required, and suggestions freely offered. There is doubtless much to praise, but there is also something to amend. It was hoped by many that the recent change of secretaryship, consequent on the lamented death of Dr. Martin, would have resulted in some infusion of freshness into the Report. This hope has been disappointed, for the present Report is, as we have said, pitched in a high strain of eulogium from start to finish. Moreover, as we have shown, the statistics are not to be implicitly trusted. The editing is careless in the extreme, the proofs having apparently been left uncorrected. Within one table of some thirty names (p. 21) we find the following misprints: Hyda-hidiform mole, Lacerated Permaimus, Hydrammos, Galachacele, urticarie, Pyamia.

MEDICAL NEWS IN BRIEF.

The Tuberculosis Exhibition in Dublin.

During the past week the Tuberculosis Exhibition in Dublin attracted large numbers of visitors of every class, particularly of members of local sanitary authorities, who took notice of the means adopted in various English and other cities to combat tuberculosis. Each day, either in the afternoon or the evening, a popular lecture was delivered by a medical or other expert qualified to speak with authority, her Excellency the Countess of Aberdeen occupying the chair at most of the lectures. On Monday evening the Registrar-General (Mr. Matheson) lectured on "Tuberculosis in Ireland." He contrasted the statistical history of tuberculosis in England, Ireland, and Scotland from the years 1864 to 1906. While in 1864 Ireland stood lowest of the three, with a rate of 2.4 per 1,000 living, the rate for England being 3.3, and that for Scotland 3.6, in 1905 Ireland occupied the unhappy position of being the highest, with a rate of 2.7, Scotland being next with 2.1, and England lowest with a rate of 1.6.

The lecturer told his audience that out of a total of 74,247 deaths registered in Ireland in 1906, no fewer than 11,756, or 15.8 per cent., were due to the disease. Amongst the classes which were well housed, clothed, and fed, the mortality from the disease was much less than among those who had not those advantages. He instanced insanitary houses and surroundings, intemperance, and neglect of precautions against infection as the main causes favouring the spread of the disease, and emphasised the necessity of the establishment of special dispensaries, sanatoria, and hospitals in order to check its growth.

Dr. Lawson, Medical Superintendent of Nordrach-on-Dee Sanatorium, chose as the title of his lecture "Some Aspects of the Tuberculosis Problem." It was illustrated by a number of limelight views. He advocated, among the measures to be adopted in coping with the evil, the provision of improved dwellings for the workers in the towns; the adoption of regulations which would render it an offence, involving a legal penalty, to expectorate in public; the inspection of the milk supply with a view to securing its purity; the compulsory notification of pulmonary tuberculosis; and the erection of two classes of buildings for the accommodation of consumptive patients—one class designed for advanced cases, where the patients might be cared for until they died, and another class to which others might go with a reasonable prospect of recovery.

Dr. McSweeney lectured on "The Campaign Against Tuberculosis in Germany," giving a résumé of the facts detailed in his well-known Report to the Local Government Board.

Mr. Lentaigne lectured on "Tuberculosis of Bones and Joints." It was most difficult, he said, to get such cases retained in general hospitals as long as they should be, and consequently real and permanent cures were far less frequent than they should be. He thought it would be well that when sanatoria were being constructed accommodation should be provided for such cases to complete their cure after a short stay in a general hospital for special surgical treatment. They might be accommodated with the pulmonary cases, but it would be better and safer when cheap wooden buildings and sheds were being erected for the purpose to have special buildings of a similar character, but with special trained nurses and some special surgical equipment for these cases. Tuberculosis was produced in three ways—by inhalation with the breath, by swallowing with food, and by inoculation. Tuberculosis by inhalation could be prevented from spreading by segregation and by the education of the public. They could prevent the infection through the medium of food by the same means, and by putting an end to the sale of infected milk. That could be done if it was made a penal offence for anyone to sell milk from animals that had not been certified free from tuberculosis. The disease would them be very soon stamped out in domestic cattle. The campaign should be one of education and agitation. They had to combat three enemies—economy, ignorance, and apathy. In order to overcome the enemy of ignorance he strongly advocated, among other measures, the imparting to children a proper health training. They should agitate for notification for suitable hospital accommodation, and for the restriction of the sale of poisonous milk.

The attendance at all the lectures was gratifying, and an interesting discussion followed each lecture.

Prosecution by the Dental Association.

At the Worcester Police Court, on October 14th, Percy Smith, Beacon View, Woolhope Road, was summoned by the British Dental Association for unlawfully using a certain description implying that he was a person specially qualified to practise dentistry. Mr. Maund appeared for defendant, who pleaded not guilty.

Counsel said the case was taken under the Dentists Act, 1878, which said a person should not be entitled to take the name of dentist or dental practitioner, implying that he was specially qualified, unless he were registered under the Act. Defendant had been employed by Mr. F. W. Sievers, a Worcester dentist, first as house-boy and then as mechanic. He had at no time during that period had experience in dental operations. He was discharged by Mr. Sievers, and soon afterwards mentioned that he had started on his own account, and handed to Mr. Sievers' cook a card, which was the cause of the prosecution. The card was as follows:—"Artificial teeth: high-class work at moderate charges; painless extractions; advice free. Mr. Percy Smith. Beacon View, Woolhope Road, Worcester. Seventeen years with Mr. F. W. Sievers, L.D.S." The Dental Association maintained the card was an infringement of the Act the object of which was to prevent unqualified persons from practising dentistry. The man implied by the card that he had had experience. Mr. Sievers said defendant was employed by him for seventeen years. He was never allowed to operate, and witness would not be allowed to employ an unqualified assistant. Mr. Maund said defendant was doing nothing that he thought was legally or morally wrong in adopting the means of advertisement others used. He had now withdrawn the card. Mr. Maund argued that the card did not necessarily imply that defendant was a registered practitioner.

Defendant was fined £2 and costs.

Royal College of Surgeons in Ireland.

The Winter Session commenced on Tuesday, October 15th, when the prizes of the previous Session were distributed by the President of the College as follows:—Barker Anatomical Prize—£31 10s., G. S. Levis. Carmichael Scholarship—£15, J. Menton. Gold Medals in Operative Surgery—P. G. M. Elvery and T. Sheehy (equal). Stoney Memorial Gold Medal in Anatomy—Miss I. M. Clarke and G. C. Sneyd (equal). Descriptive Anatomy—Junior—J. T. Duncan, 1st prize (£2) and medal; T. Dowzer, 2nd prize (£1) and certificate. Senior—H. G. P. Armitage, 1st prize (£2) and medal; W. Swan, 2nd prize (£1) and certificate. Practical Anatomy—First Year—T. M. Thomson, 1st prize (£2) and medal; F. W. Warren, 2nd prize (£1) and certificate. Second Year—W. Swan, 1st prize (£2) and medal; H. G. P. Armitage, 2nd prize (£1) and certificate. Practice of Medicine—C. Greer, 1st prize (£2) and medal; G. S. Levis, 2nd prize (£1) and certificate. Surgery—G. S. Levis, 1st prize (£2) and medal; W. R. Burton, 2nd prize (£1) and certificate. Midwifery—H. W. White, 1st prize (£2) and medal; G. S. Levis, 2nd prize (£1) and certificate. Physiology—H. M. E. H. M'Adoo, 1st prize (£2) and medal; O. G. Connell, 2nd prize (£1) and certificate. Chemistry—P. V. Crowe, 1st prize (£2) and medal; J. T. Duncan, 2nd prize (£1) and certificate. Pathology—I. Scher, 1st prize (£2) and medal; C. Greer, 2nd prize (£1) and certificate. Physics—J. T. Duncan, 1st prize (£2) and medal; T. Buckley, 2nd prize (£1) and certificate. Practical Histology—F. W. Warren, 1st prize (£2) and medal; J. S. Pegum, 2nd prize (£1) and certificate. Practical Chemistry—H. C. Gilmore and J. Kirker (equal), 1st prize (£2) and medal. Public Health and Forensic Medicine—H. Hunt, 1st prize (£2) and medal; Miss C. F. Williamson, 2nd prize (£1) and certificate. Materia Medica—J. Menton, 1st prize (£2) and medal; Miss C. F. Williamson, 2nd prize (£1) and certificate. Biology—J. T. Duncan, 1st prize (£2) and medal; P. V. Crowe, 2nd prize (£1) and certificate.

The Royal College of Physicians of Ireland.

The annual meeting of this College was held on St. Luke's Day. The President, Censors, Examiners, and other officers for the ensuing year were elected as follows:—

President—Dr. Joseph M. Redmond. Censors—Drs. Norman, Murphy, Jellett, and R. Travers Smith. Vice-President—Dr. Norman.

Additional Examiners to take the place of an absent Censor:—Medicine—Dr. Matson. Medical Jurisprudence and Hygiene—Dr. Montgomery. Midwifery—Dr. Glenn. Examiners in Midwifery—Dr. Horne, Dr. Wilson. Examiners, in addition to Censors, under the Conjoint Scheme: — Biology — Dr. Kirkpatrick. Chemistry—Dr. Lapper, Dr. Falkiner. Physics—Dr. Peacocke, Dr. Winter. Pharmacy, Materia Medica, and Therapeutics—Dr. Drury, Dr. Dempsey. Physiology—Dr. Earl. Pathology—Dr. F. C. Purser. Medicine—Dr. Parsons, Dr. W. J. Thompson. Hygiene and Forensic Medicine—Dr. Dawson. College Examiners for the Conjoint Preliminary Examination:—Mr. E. H. Alton, F.T.C.D., Mr. R. A. P. Rogers, F.T.C.D., Dr. Connor Maguire. Examiners for the Conjoint Diploma in Public Health:—Hygiene—Dr. Bewley. Chemistry—Dr. Lapper. Meteorology—Dr. Winter. Examiners for the Membership:—Clinical Medicine—Dr Wallace Beatty, Dr. Murphy. Practice of Medicine—Dr. O'Carroll, Dr. R. Travers Smith. Pathology.—Dr. Earl, Dr. O'Sullivan.

Dr. James Spencer Sheill, M.R.C.P. and L.R.C.S.I., was elected a Fellow of the College.

The annual dinner of the College was held on Saturday, the 19th inst., in the College Hall, and was largely attended. Amongst the guests were Lord Justice Holmes, the Master of the Rolls, the Provost of Trinity College, the President of the Royal College of Surgeons, the President of the Royal Irish Academy, the President of the Royal Irish Academy of Medicine, his Honour Judge Craig, Sir Charles Ball, Mr. Harrington, M.P., Sergeant O'Connor. The toasts consisted of "The King," "The Guests," "The Sister College," "The President," "The Registrar."

Haslar Hospital.

The course of instruction at Haslar Hospital for the naval surgeons who entered at the spring competitive examination has just come to an end, and the usual awards have been made to the three surgeons who have so far most distinguished themselves. Surgeon R. Connell, M.B. (Trinity College, Dublin), has gained the gold medal, and Surgeon C. Ross (Glasgow University) the silver medal, whilst the third award, in the form of a handsome microscope, has been made to Surgeon G. Price, a former student of St. Thomas's Hospital.

The Medical Exhibition.

In our report and description last week of exhibits at the Medical Exhibition held in London, we referred to the recently introduced preparation "Miol" as an emulsion of cod liver oil and malt. This was a slight slip of the pen for olive oil and malt, a decidedly useful therapeutic novelty, one which doubtless will be duly appreciated by the profession when better known.

PASS LISTS.

Conjoint Examinations in Ireland by the Royal College of Physicians and Surgeons.

The following candidates have passed the first Professional Examination, October, 1907:—

M. L. Bourke, F. E. Fitzmaurice, J. M. Gilmore, C. H. Joynt, J. Kirker, C. J. Kelly, A. G. J. MacIlwaine, B. Malaher, B. Murphy, D. McDevit, B. Neary, A. J. Neilan, M. K. O'Byrne, J. H. Rishworth, C. Roche, G. Wilson, and G. Young.

The following candidates have passed the Preliminary Examination:—

J. T. McConkey (with honours), J. I. Pollock (with honours), W. I. Adams, A. C. J. Austin, A. J. Bodell, G. Bailey, A. T. Cannon, G. Campbell, T. F. Collins, D. Dudley, A. P. Flood, P. A. Gardner, R. M. Gordon, S. Griffin, D. J. Healy, N. S. Hood, T. Kennedy, W. J. Marmion, M. Meehan, D. Murphy, J. J. Murphy, A. J. Patterson, F. P. Shields, M. Scher.

Copies of the Preliminary Regulations for 1908 can now be obtained on application.

The Royal University of Ireland.—Medical Degrees Examinations.

The following candidates have passed the undermentioned examinations:—

The M.D. Degree Examination.—Thomas Barry, M.B., B.Ch., B.A.O.; Robert Chambers, M.B., M.B.B.Ch., B.A.O.; Foster Coates, B.A., M.B., B.Ch., B.A.O.; William J. Maguire, B.A., M.B., B.Ch., B.A.O.; James B. Slattery, M.B., B.Ch., B.A.O.; Robert Steen, M.B., B.Ch., B.A.O.; William J. Wilson, B.A., M.B., B.Ch., B.A.O.

The M.B., B.Ch., B.A.O. Degrees Examination.—Upper Pass.—Thomas S. S. Holmes, James B. Lapsley, John E. A. Lynham, B.A., William D. O'Kelly, Herbert H. Prentiss, James Shaw, James A. Shorten, B.A., Alexander L. Stevenson.

Pass.—Joseph H. P. Boyd-Barrett, Edwin B. Brooke, Matthew F. Caldwell, Gault Calwell, William F. A. Carson, Robert Cox, B.A., James Dewar, Michael F. Donovan, B.A., James J. Flood, Charles E. L. Harding, John J. Hickey, James Horgan, James B. Horgan, John Hughes, Francis Keane, Joseph P. Kerlin, Richard R. Kirwan, Thomas J. McAllen, John S. McCombe, Wiclif McCready, Augustine P. MacMahon, John J. O'Reilly, Christopher F. X. O'Sullivan, Daniel T. Sheehan, James Sinclair, Hans C. Swertz.

The following candidates are exempted from further examination in the subjects set after their names:—Robert G. Kevin, the Medicine Group; John F. Neary, the Medicine and Midwifery Groups.

The following candidates may present themselves for the further examination for Honours in the groups mentioned after their names:—James B. Lapsley, the Medicine Group; William D. O'Kelly, the Midwifery Group; Herbert H. Prentiss, the Medicine, Surgery and Midwifery Groups; Daniel T. Sheehan, the Midwifery Group; James A. Shorten, B.A., the Medicine and Surgery Groups; Alexander L. Stevenson, the Medicine and Surgery Groups.

Royal College of Surgeons of Edinburgh.

At the annual meeting, held on 16th inst., Mr. Joseph Montagu Cotterill was unanimously elected President for the ensuing year. At the same meeting the following gentlemen, having passed the requisite examinations, were elected ordinary Fellows of the College:—

William Rickward Bacot, M.R.C.S.Eng., London, W.; Harold Graves Bennetts, M.B., C.M., Sydney, N.S.W.; Gerald Hall Lloyd Fitzwilliams, M.B., Ch.B., Newcastle Emlyn, S. Wales; James Methuen Graham, M.B., Ch.B., Edinburgh; William Ezra Graham, M.D., C.M., Ontario, Canada; Duncan Lorimer, M.B., Ch.B., Edinburgh; Peter McEwan, M.B., Ch.B., Kinfauns, Perthshire; William Latto Robertson, L.R.C.S.E., M.B., Ch.B., Edinburgh; William Craig Stewart, M.B., Ch.B., Glasgow, W.; and Stanley Martin Wells, M.R.C.S.Eng., Lima, Peru, South America; and John Pinkerton, M.D., etc., Honorary Physician to his Majesty the King, Gwydyr House, Crieff, Perthshire, was admitted an Ordinary Fellow without examination.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

***Specially compiled for* THE MEDICAL PRESS AND CIRCULAR.**

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Ruptured Pus Tubes.—Mann (*Amer. Jour. Obst. and Gynæ.*, October, 1907).—Clinically ruptured pus tubes may be divided into three classes: (1) Those which rupture into the peritoneal cavity, but in which the pus is restrained by adhesions from setting up a general peritonitis. (2) Those which rupture into some adherent viscus—as the bladder, rectum, intestines. (3) Those in which the rupture is into the peritoneal cavity, the pus not being walled off, and, if virulent, setting up a general peritonitis which acts much like an acute ruptured appendicitis, and usually causes death, unless operative means are employed. It is, however, more amenable to operative measures than peritonitis caused by appendicitis. By far the most common class is the first, the pus escaping forming an abscess which often reaches above the umbilicus, and contains a quart or more of pus, this finally rupturing into the bowel, or peritoneal cavity, or causing death by absorption of toxins. In the second class the danger of secondary infection through the sinus is great, and complete cure is obtained only by removal of the tube and closure of the sinus opening. Of the third class, when symptoms of peritonitis begin, to temporise is, in the writer's opinion, not giving the patient the best chance, and therefore that operation and drainage is in order even in the acute stages. F.

Blood Transfusion in Puerperal Septicæmia.—McKay (*Amer. Jour. Obst.*, October, 1907). The writer reports a case in order to show that the rigors of puerperal septicæmia may be abolished by the transfusion of blood, and to point out the negative effect of enormous infections of antitoxin in this case. The case was admitted to hospital on the fifth day after premature labour; examination of uterine discharge showed a streptococcic infection. Antistreptococcic serum was injected with no result. Having found in previous experience that the antidiphtheritic serum seemed to act well when the antistreptococcic serum failed, he gave her 2,000 units of these sera alternately every four hours. The patient grew steadily worse, and the antitoxin was increased. Rigors began on the fourth day after admission, and continued daily till the joint transfusion of blood and saline. After this transfusion—in which not more than a few ounces of blood was employed—the rigors disappeared for six days, then began again. Thinking that perhaps the salt solution had brought about the happy result, a vein was opened, and thirty ounces of normal saline, to which one ounce of peroxide of hydrogen had been added, was introduced. The patient had a most severe rigor forty-eight hours later, the temperature rising to 106 deg. On the following day ten ounces of blood and twenty ounces of normal saline were transfused, and the patient had no more rigors for twelve days, during which time the pulse and temperature improved, and the patient progressed so rapidly that she was allowed to sit up in bed. Whilst in this posture she fainted, and died in a few minutes. F.

Retention in Utero of Separated After-coming Head.—McKerron (*Jour. Obst. and Gyn.*, October, 1907). Separation of the after-coming head, with retention in utero, is probably a not uncommon accident, while it usually occurs in the case of long dead decomposing children, in whom the tissues are very friable. When the complication occurs the delivery of the head is often a matter of considerable difficulty, and more especially when its extraction has not been undertaken at once, and the os uteri has had time to retract. In view of the comparative frequency of this accident, and of the difficulties that may attend extraction, it is surprising that few writers and no text book refer to it. There are several ways in which extraction of the retained head may be effected. Sometimes expulsion is completed spontaneously, but this is exceptional. The selection of a method of extraction will depend on the extent of dilatation, and on the dilatability of the cervix uteri. When the case is seen at once, before the cervix has retracted, firm downward pressure on the fundus may be sufficient, either alone or combined with moderate traction on the head by the hand or volsella. It is seldom separation takes place at the immediate base of the skull; a part of the cervical column is usually left, and affords a good hold for the hand. Where the cervical vertebræ are torn off, traction may be made in the lower jaw, but this even may tear off. Then delivery must be effected by getting the tip of index finger through the foramen magnum, or by making traction by means of forceps or volsella. When the cervix is imperfectly dilated, or is rigid and unyielding, great difficulty may be experienced in effecting extraction. The cervix must first be dilated, then if a good grasp of the head cannot be obtained with the hand, the volsella, with pressure from above, may be tried; but if much force is required, it is not likely to be successful. owing to the friability of the tissues. Should they fail the forceps may be tried, and its application assisted by steadying the head from above. In the event of failure with the forceps, the cephalotribe or cranioclast, both of which have been successfully used, may be tried. Bergués, in a recent paper on the subject, recommends when the cervix has become retracted, that the head should be fixed by means of a volsella, to which a weighted cord is attached, and allowed to hang over the end of the bed. The continuous traction induces contractions of the uterus, dilatation is thus secured, after which the head can be delivered by traction on the volsella. F.

Ventral Hysteropexy.—Olshausen (*Zentralbl. für Gynäk.*, 1907, No. 41) describes his method modified by his former assistant, Professor Koblanck, which has been employed in his klinik during the last ten years. After opening the abdomen, the skin and adipose tissue are separated from the rectal fascia by a few strokes of the knife at each side of the abdominal incision. A needle with a thick silkworm gut suture is then passed from the superior surface of the bared fascia through the remainder of the abdominal wall into the abdominal cavity. The needle point is inserted about 2 cm. external to the incision, and before passing the needle through, it is important to see that the peritoneum and fascia are pulled well into the incision on each side, so that they may come together easily during the closure of the abdomen. When the needle has been passed into the abdomen it is picked up and guided through the origin of the round ligament, taking up underneath the latter a little of the muscle of the uterine cornu. It is then passed back from within outwards through the abdominal wall, the point being inserted a few centimetres distant from the former point of entry. The suture is then tied. The knot is thus on the superior surface of the fascia. Before the knot is tied one must be certain that the cornu of the uterus lies closely against the abdominal wall. The same proceeding is to be followed on the other side. The operation has been performed hundreds of times in Olshausen's klinik, with excellent results. When it is properly performed it is practically impossible to get a recurrence. The only time a possibility of a recurrence arises is when the silkworm gut suture is tied so very tightly that it cuts through the fascia. The silkworm gut does not alter, therefore it is the best suture material. Olshausen has never seen any hindrance to the development of the uterus during pregnancy after this operation. Neither has he ever seen the operation followed by an abortion. It has been reported that he had a case of intestinal obstruction following this operation, but this is not true. As regards ventral fixation in cases of prolapse of the uterus, he very seldom performs this operation, and then only in combination with colporrhaphy, etc. In such cases, in addition to the silkworm gut suture on each side, he puts in a catgut suture in order to get a broader attachment between the uterus and the abdominal wall. G.

Epilepsy and Pregnancy.—Neu (*Monatssch. für Geb. und Gyn.*, Bd. XXVI., Hft. I.) describes a case as follows:—A primipara, æt. 24, developed epilepsy in the sixth month of her pregnancy. She had 26 fits in 23 hours. As a result she became comatose, and died without regaining consciousness, but with all the symptoms of œdema of the lungs. The patient had suffered before her pregnancy from epilepsy. The author then discusses very thoroughly the relationship between epilepsy and pregnancy. It is his opinion that pregnancy is not the primary cause of the epilepsy, but that epilepsy can be influenced by pregnancy. Whether in cases of pregnancy complicated by epilepsy labour should be induced or not, must be decided by observation of the cases individually. Induction will very often be indicated when the convulsions are very numerous, and always in every case of status epilepticus. G.

Suprapubic Delivery and its Relationship to Other Operations in Cases of Contracted Pelvis.—In a paper on this subject, Frank (*Archiv. für Gynäk.*, Bd. LXXXI., Hft. I.) agrees with the views of Kehrer on the superiority of the low incision in Cæsarean sections. The greatest danger still consists in the infection of the peritoneum from the uterine cavity. If this could be prevented the Cæsarean section becomes an operation free from danger which would certainly reduce the number of operations which are performed for artificially enlarging the pelvis, and also there would be a greater freedom of choice as regards the time at which the Cæsarean section could be performed. The author considers that all this may be obtained by his suprapubic method of delivery by which the abdominal cavity is definitely shut off before the incision into the uterus is made. A transverse incision is made two fingers breath above the symphysis, and directly above the bladder. After the abdomen is opened, the loose fold of peritoneum on the uterus is picked up, cut across transversely, and its upper border is sutured to the parietal peritoneum of the upper edge of the wound. When this has been carefully completed a transverse incision is made in the region of the lower uterine segment. The head is usually spontaneously delivered—one may even wait for spontaneous deliverance by the pains. The author can report from a series of thirteen cases, which were all of a very doubtful nature as regards asepsis, in which the results for the mothers were excellent. It is also his opinion that when suprapubic delivery has been fully developed, it will cause a disappearance in cases of contracted pelvis, of induction of abortion, induction of premature labour, the perforation of the living child, and the sterilisation of women. For infected parturient women whose natural powers have worked in vain, and for whom also the operations for enlarging the pelvis are not without danger, and are also not permissible for every degree of pelvic contraction, this method of delivery is one which may be employed without danger to save the mother and child. G.

Cæsarean Section when the Uterus is Infected—Relying upon the statement of Frank, the Cæsarean section was performed by Veit (*Monatssch. für Geb. und Gyn.*, Bd. XXVI., Hft. I) for two women whose liquor amnii was infected. In order to prevent infection of the peritoneal cavity by the liquor amnii, he sutured the peritoneum of the uterus to the parietal peritoneum after dividing the abdominal wall transversely. Having opened the lower uterine segment, he removed the contents of the uterus and sutured the incisions. He is quite content with the result of the operation in both cases, but advises that the operation shall not be done too early, as good dilatation of the lower uterine segment is desirable. He regards this method of Cæsarean section as most important in cases of decomposition of the uterine contents, as it prevents the entrance of the infection into the abdominal cavity. G.

Complications of Retroflexio Uteri, and their Influence on the Operative Treatment.—In a paper on this subject, Guggisberg (*Zentralbl. für Gynäk.*, 1907, Nr. 41) discusses the ætiology and the symptoms of retroflexio uteri. He then speaks of the complications which may affect the myometrium, the endometrium, the perimetrium, and, further, the adnexa, whose diseases he attributes to the congested condition of the genitals. Among 176 patients who were operated on in the Bern klinik, 60 had complications. The majority of the women dated their sufferings from an afebrile puerperium. The principal symptoms are sacral pain and hæmorrhage. The complications: endometritis, metritis, perimetritis, and, finally, diseases of the adnexa either inflammatory or degenerative. The latter were frequently not diagnosed. As regards the indications for treatment, one must first exclude hysteria, and it must then be determined whether the symptoms are due to the displacement or to the complications. Operative treatment is indicated when the pessary does not work, or causes pain, or when its insertion is not desirable. When operation is decided on, the endometrium must especially be subjected to energetic treatment. Then, having opened the abdomen by the transverse incision, after inspection, and, if necessary, treatment of the adnexa, the round ligaments are fixed to the anterior abdominal wall by one or two silkworm gut sutures which go through the peritoneum, the recti, and the fascia. G.

Alcohol in Midwifery and Gynæcology.—Theilhaber (*Münchener Med. Wochensch.*, 1907. Nr. 4).—In pregnancy, during labour, during puerperal fever, and during lactation, alcohol enjoys the reputation of being a therapeutic agent of value. In all those conditions the author declares that this reputation is unjust, since the action of the alcohol is more injurious than beneficial. It is just as injurious in gynæcology. It causes hyperæmia of the female genitals, it increases the sexual desire, it increases the secretions from the genital system, and also the amount of menstrual hæmorrhage. He forbids, therefore, that it should be given to young girls, to those with diseases producing hæmorrhage and secretions, for all pelvic neuroses, and for the symptoms associated with the menopause. In cases of chlorosis and anæmia there is nothing to be gained by the administration of red wine. Physicians should join in the crusade against alcohol. They can do much by limiting the prescribing of alcoholic drinks. G.

The Chelsea Hospital for Women has received from Earl Cadogan a donation of £500, and the Council have resolved to name a ward of the hospital in memory of its late benefactress, the Countess Cadogan.

Dr. Thomas, the Medical Officer of Health for the Borough of Stepney, reported recently that in the parish of St. George's-in-the-East, the centre of the alien immigration in the East End, the birth-rate for the past fortnight was as high as 52 per 1,000, practically double that for the whole of London.

The annual surgical report of the Netley Hospital shows that 1,282 were treated in twelve months. The number returned to duty was 791, whilst 357 were invalided. The number of deaths was 14, and the balance of admissions remained under treatment. Out of 220 surgical operations no fewer than 190 were completely successful, whilst 17 were partially successful, and 13 were failures, chiefly owing to the weakness of the patient.

A sub-committee decided on Monday afternoon to recommend the Public Health Committee of Dundee Town Council to adopt the Notification of Births Act. The Act provides that notification shall be given to the Medical Officer of Health, and failure to comply with the Act is punishable by a penalty of 20s. The principal idea of notification is that the Medical Officer may send health visitors to any house after the birth of a child, and in this way assist the mother to build up a healthy child at the very outset.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

WHAT IS IN A NAME?

THE limits of the ominous in the physician's name are surely reached in the case reported from Sheffield in the following note:—It may interest you to know that we have here a Dr. Kilham. Also there is a Dr. Reckless, of long-standing connection here. The initial letter of his Christian name being A, for Arthur, his name-plate used to read, "A. Reckless, Surgeon." But he had it altered to his full name.

After this the "Coffins" and the "Philgraves" cease to move our admiration. The Kilham who enters the medical profession demonstrates the invincibility of the human will as few men have done it.—*Daily News.*

ANXIOUS (Exeter).—It is always best, under the circumstances, to submit the case to a consultant. The question of fee could no doubt be arranged to meet the position of the patient.

OSLERISMS.

"EXAMINATIONS are merely the meeting of certain tests. They make a man a mere talking machine or a human monotype."

"Take no thought for the morrow. Let the interest of the day's work absorb all your energies."

"Be sceptical to the Pharmacopœia as a whole. He is the best doctor who knows the worthlessness of most medicine."

"Study your fellow-man—and fellow-woman; and learn to manage them."

"Once get down to the purely business level and your influence is gone, and the light of your life goes out."

DR. S. C. Y.—An X-Ray examination of the limb should undoubtedly be made. Without it there can be no certainty as to the real condition of affairs.

SPES (Birkenhead).—There is nothing in the course pursued by our correspondent which we regard as being derogatory in a professional respect.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 23RD.

ROYAL SOCIETY OF MEDICINE (SURGICAL SECTION IN CONJUNCTION WITH THE CLINICAL LARYNGOLOGICAL, MEDICAL, AND OBSTETRICAL SECTIONS).—5.30 p.m.: Special Meeting. Demonstration (by means of the epidiascope and microscopes):—Prof. Goldman (Freiburg): (1) The Growth of Malignant Disease in Man and the Lower Animals, with Special Reference to the Vascular System; (2) The Diagnosis, by the help of the X-Rays, of Abdominal Malignant Disease, Subphrenic Abscess, Appendicitis, etc.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Pardoe: Clinique. (Surgical.) 5.15 p.m.: Lecture: Dr. D. Drummond (Newcastle-on-Tyne): The Mental Origin of Neurasthenia and its bearing on Treatment.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

THURSDAY, OCTOBER 24TH.

CHILD STUDY SOCIETY (Parkes Museum, Margaret Street, W.).—8 p.m.: Lecture:—Dr. C. A. Mercier: Principles of Education.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. D. Drummond (Newcastle-on-Tyne): The Diagnosis of Thoracic Aneurysm.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson), X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture Demonstration:—Dr. T. R. Whipham: Children's Diseases.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: The Treatment of Eczema in all its Forms.

FRIDAY, OCTOBER 25TH.

ROYAL SOCIETY OF MEDICINE (EPIDEMIOLOGICAL SECTION) (20 Hanover Square, W.).—7.45 p.m.: Council Meeting. 8.30 p.m.: Presidential Address:—Dr. Newsholme: Poverty and Disease as illustrated by the Course of Typhus Fever and Phthisis in Ireland.

ROYAL SOCIETY OF MEDICINE (ELECTRO-THERAPEUTICAL SECTION) (20 Hanover Square, W.).—8.30 p.m.: President's Address.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. D. Grant: Clinique. (Ear.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Appointments

BELL, W. W., L.S.A., Clinical Assistant to St. John's Hospital for Diseases of the Skin, London.

BRAY, P. D., M.R.C.S., L.S.A., Clinical Assistant to the Chelsea Hospital for Women.

BROWN, A. CARNARVON, M.R.C.S., L.R.C.P.Lond., Resident Medical Officer at the Farringdon General Dispensary and Lying-in Charity, Holborn Circus, London.

COWAN, J., M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the New Galloway District of the county of Kirkcudbright.

DAVIDSON, JAMES A., M.B., Ch.B.Aberd., Junior House Surgeon at the Croydon General Hospital.

JONES, ERNEST, M.D., B.S.Lond., M.R.C.S.Lond., D.P.H.Cantab., Registrar and Pathologist to the West-End Hospital for Diseases of the Nervous System.

LAVERICK, F. R. H., M.D., B.S.Durh., House Surgeon to the Torbay Hospital, Torquay.

PORTER, W., M.B., B.S.R.U.I., Certifying Surgeon under the Factory and Workshop Act for the Portrush District of the county of Antrim.

RICE, D., M.D.Brux., M.R.C.S., L.R.C.P.Lond., Resident Medical Superintendent at the Norwich City Asylum.

THOMAS, W., M.R.C.S., L.R.C.P., Medical Officer and Public Vaccinator for the Third District by the Liskeard (Cornwall) Board of Guardians.

TURTON, EDWARD, M.D., Ch.B., B.Sc.Vict., M.D.Leeds, M.R.C.P. Lond., Honorary Physician to the Hull Royal Infirmary.

WARREN, A. C., M.R.C.S., L.R.C.P.Lond., Clinical Assistant to the Chelsea Hospital for Women.

Vacancies.

Bristol Royal Infirmary.—House Surgeon. Salary, £100 per annum, with apartments, board, and laundry. Applications to W. E. Budgett, Secretary and House Governor.

Bristol Royal Infirmary.—House Physician Salary, £100 per annum, with apartments, board, and laundry. Applications to W. E. Budgett, Secretary and House Governor.

Rochester St. Bartholomew's Hospital.—House Physician. Salary, £110 per annum, with board and residence at the Hospital. Applications to Thos. Crockford, Clerk to the House Committee.

Lancaster County Lunatic Asylum.—Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications to Medical Superintendent.

Birmingham General Dispensary.—Resident Surgeons. Salary, £150 per annum, with furnished rooms, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary.

Holborn Union.—Assistant Medical Officer. Salary, £100 per annum. Applications to J. Allan Battersby, Clerk to the Board, Guardians' Offices, 53, Clerkenwell Road, E.C.

The Children's Hospital, Dublin.—Assistant Surgeon. Immediate applications to Hon. Sec., Temple Street.

Births.

RICHMOND.—On Oct. 20, at 57, Drayton Gardens, London, the wife of W. Stephenson Richmond, M.R.C.S.Eng., of a son.

JEANS.—On Oct. 13th, at 43 Canning Street, Liverpool, the wife of Frank A. G. Jeans, M.B., F.R.C.S., of a son.

WOLFE.—On Oct. 16th, at Hanwell, London, the wife of John Henry Wolfe, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

WOOD.—On Oct. 16th, at Emotts, Penshurst, Kent, the wife of W. Charrington Wood, M.D.Lond., F.R.C.S.Eng., of a daughter.

Marriages.

COLLINS—BRANDT.—On Oct. 16th, in All Saints' Church, Cheltenham, J. Rupert Collins, M.D., to Agnes Mary, younger daughter of Mr. Francis Brandt, J.P., (I.C.S., retired), of Cheltenham.

EVANS—DAVIS.—On Sept. 21st, at Bombay Cathedral, Major Usher W. Evans, R.E., second son of Usher W. Evans, M.D., Dy. Inspect.-Genrl., of Clifton, to Gertrude Julia, younger daughter of the Rev. W. Smith Davis, late Rector of Steeple Gidding, Huntingdonshire.

FLOOD—PITKIN.—On Oct. 17th, at St. Mary's, Shapwick, Somerset Frederick Grey Flood, M.R.C.S., L.R.C.P., of Wymeswold, Leicestershire, only son of the late Alfred John Flood, banker, of Witney, Oxon., to Ruth, youngest daughter of Rev. J. Pitkin.

HARRIES—LYON.—On Thursday, Oct. 17th, Arthur J. Harries, M.D., of 30 St. James's Square, Pall Mall, London, S.W., to Clara, widow of the late Reuben Lyon, formerly of Johannesburg, South Africa. No cards.

KINGSBURY—HOLLAND.—On Oct. 17th, at St. James's Church, Paddington, William Neave Kingsbury, M.R.C.S., L.R.C.P., eldest son of W. G. Kingsbury, of Ealing, to Marion, younger daughter of the late George Holland, of Sandbach, Cheshire.

Deaths.

HOILE.—On Oct. 18th, at 112, Oakwood Court, Kensington, Lieut.-Col. Edmond Hoile, M.D., late of the 17th Lancers.

SIMON.—On Oct. 16th, at the residence of his daughter, Whitehall, Pembroke, George Simon, M.D., Lt.-Col. A.M.S., Hon. Brig.-Surg., aged 70 years.

STEPHENS.—On Oct. 17th, at Preston, Brighton, Helen Wordsworth, wife of J. Stephens, L.R.C.P., late of Old Steine, Brighton.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, OCT. 30, 1907. No. 18

NOTES AND COMMENTS.

The Speed Limit. How fast may a medical man drive his motor? This question is one which is likely to be more and more debated in the course of the next few years. The bulk of the profession has little enough sympathy with the road-hog, be he medical or lay, but just as the King is above the law, so the dictates of humanity are higher than police regulations, and in certain cases constitute a legitimate excuse for exceeding the speed limit. In the South-Western police-court recently the chauffeur of a medical man was summoned for driving a motor containing his master at an excessive speed on the road beside Wimbledon Common, the police estimate placing the pace at 28 miles an hour. The owner did not deny the soft impeachment, but boldly claimed his right to travel as fast as he could along an open road when called to an urgent case of illness. Mr. de Grey, the magistrate, with good sense, recognised the force of the argument and dismissed the summons. We beg to congratulate him on his discrimination. Medical men have several times been summoned under similar circumstances in different parts of the country, but we do not remember ever to have heard it admitted by the Bench that the excuse of humanity was reasonable. This case, then, should prove a valuable precedent to country Shallows.

Justifiable Excess. BUT if this privilege is claimed by the profession, and is granted to them by the sense of the community, it is most important that it should never be abused. A form of travelling which at the present calculated rate, kills a thousand persons and maims over fifty thousand a year in this country, adds a very real danger and terror to the lives of the mass of the people, and improper and reckless driving certainly deserves the most heinous penalties. If then a medical man claims exemption in case of emergency, it might not be a bad plan if he were summoned whenever the legal speed was exceeded, and if excused by the magistrate on the ground of an urgent call to a patient, the latter were made to pay all the expenses of the prosecution, together with an adequate fee to the doctor for the loss of time involved in attending the Court. By some such means as this it might be possible to regulate the number of "urgent" summonses to patients, and thus relieve the general practitioner's life of its heaviest load.

From Christian Science to Medicine. IT has been thought a matter of such moment to the world that a Christian Scientist in America should call in a doctor, that a Marconi wireless message was employed to flash the fact to this country. The doubting sister in question, Mrs. Augusta Stetson, is, it happens, a candidate for the leadership of the faithful in the presumably impossible event of Mrs. Eddy being called "up higher"; at any rate, she is regarded as a kind of second string, and her bad example is likely therefore to have a powerful influence on the shaky members of the flock, though doubtless amongst the real believers it will be regarded merely as an act of magnaminity such as one practitioner might show to another. The Christian Scientists in America have gradually been adding to the occasions on which a doctor may be called in ever since the day when Mrs. Eddy had toothache, and was found Nicodemus-like repairing to the dentist. Some three years or so ago medical aid was permitted in the case of infectious diseases, and lately we understand doctors were officially permitted when Christian Science had failed. Perhaps we shall soon find these enthusiastic idealists ranging themselves under the orthodox banner, and being sent by medical men to persuade their troublesome patients that there is nothing wrong with them except *febris imaginata*.

Vivisection Commission's Difficulties. WE find that in these notes the other day we did something of an injustice to the *Morning Leader* when we chaffed it about the "Vivisection Horror" that it had dug out of the report of the Royal Commission on Vivisection. We stated then that that ably-edited journal had adopted the short and picturesque way of supporting its views on experimentation by pasting large upon its sheet the incident of the four puppies. Our attention has been called to the fact that two articles in which Mr. Coleridge's evidence was dealt with had also appeared. We have read these articles with interest, and can certainly say that the best is made of the extraordinarily puzzling statements of that doughty protagonist. But we cannot say that we think the Commissioners have been greatly helped along their way. It is the duty of Royal Commissioners eventually to make a report, and we do not envy the present ones their task. There are only two suggestions that appear to us possible, namely, an increase of the inspectorate, and some alteration in or addition to the body that advises the Home Office as to candidates' claims for licenses. No doubt it is humanly impossible for the present inspector, Professor Thane, to be present at a tithe of the experiments performed; indeed, to compass that end a small army of officials who understand the points involved in anæsthesia, physiology, pharmacology, and pathology, would be needed. At any such proposal we fancy the economists would cry out.

Usque ad Aras. EXPERIMENTERS themselves having nothing to fear from increased publicity would have no objection, *quâ* experimenters, to the presence of any number of inspectors, though as taxpayers they might be inclined to grumble. Then, too, they could have no cause to complain of any impartial body, which understood the issues at stake, giving advice to the Home Office on the capabilities of would-be experimenters to ascertain truth from experiments and to carry them out with humanity and skill. But what better body could be chosen than the present one? It would hardly be contended that a committee composed of Mr. Coleridge, Miss Lind-af-Hageby, Miss Beatrice Kidd, and Dr. Hadwen, would be competent for the task. Besides, after the committee had been sitting a month, we fear that as in the tragedy of the Kilkenny cats nothing but tails would be left.

The M.A.B. and its Matrons. THERE is a sad time in store for the Metropolitan Asylums Board. That body, it appears, proposes that the matrons of its hospitals shall no longer be first-class officers, but shall serve their common task in the less Olympian sphere of the second class. The full heinousness of this proposal will not be apparent to outsiders till it is realised that this revolutionary proposal actually means that the matron is to rank no longer with the medical superintendent, but with the assistant medical officers, and that the nursing administration of the hospials will be pulled down to the level of the mere medical treatment of patients. No wonder that an emergency meeting of the Matrons' Council for Great Britain and Ireland was called at forty-eight hours' notice and that the room was crammed to suffocation. No wonder that the fair president proposed a resolution calling the attention of the public, the Local Government Board, and the nursing profession to this attempted degradation. No wonder that the motion was carried with the utmost enthusiasm. But the matrons are not going to stand any nonsense. They threaten the unlucky Board with a boycott, also agreed to unanimously, and they have represented to the President of the Local Government Board the advisability of receiving a "small deputation," lest he should not understand the "widespread and prejudicial effects" that the change will cause.

A Plea for Justice. INDEED, the matrons are so excited that they say they feel themselves incompetent to show clearly in a letter all that they feel, and it really seems that if Mr. Burns declines to override the Metropolitan Asylums Board we shall have to be on the look out for relays of mounted police to protect him from the suffragette-like importunity of these indignant ladies. At any rate, let us hope that in this crisis in the affairs of the nation Mr. Burns may keep a cool head, and that he may be led to perceive the anomaly of allowing the matrons to fall so low as the rank of mere doctors. But we would implore the Metropolitan Asylums Board, if it consents to this "degradation," that it will at least grant the matrons the privilege, now so sumptuously enjoyed by the assistant medical officers, of being "rationed as a principal officers." Dreadful things may happen if the matrons are let down in rank, but who can conceive the result if they were contemporaneously docked of their tea and sugar?

A DEATH from cholera has taken place at Lemberg, and has caused great alarm among the authorities, who have promptly formed a cholera commission. Four deaths have already occurred at Kieff.

LEADING ARTICLE.

THE TUBERCULOSIS PROBLEM IN IRELAND.

IT is a serious matter to the health of Ireland that sanitary affairs in that country are taken so lightly. In nearly every point as regards sanitary administration she is far behind the sister countries, though, indeed, in one particular she shows an example which England might well follow. We refer to protection against small-pox. Ireland has a thoroughly vaccinated population, and it is gratifying that the fads and superstitions which in England have led to such disastrous outbreaks of small-pox, are in Ireland without any upholders. In other particulars Ireland is not merely behind the rest of the Kingdom, but behind the civilised world. Her capital, with the sinister boast of being the most unhealthy in Europe except St. Petersburg, does not possess a whole-time medical officer of health! This seeming incapacity to deal with sanitary problems is nowhere better exemplified than in regard to tuberculosis. The death-rate from tuberculosis has in Ireland shown a slight increase during the past forty years, whereas the death-rate from the disease in England, Scotland, and Germany, has diminished by nearly a half. The number of deaths in Ireland each year from tubercular diseases is nearer twelve than eleven thousand, and up to the last year or two it is the bare fact that nothing was done to face the problem. There is no need to attempt to fix the responsibility for this scandal, since everyone concerned is responsible in some degree. The medical officers of health are more to be pitied than blamed, on account of the conditions of their service. Their sanitary work is secondary only to their work as dispensary medical officers, and they are in all cases dependent for their living on the good-will of the people among whom they live. Many of them have done in this, as in other directions, noble work, but power to deal with the problem as a whole has been lacking. Of the sanitary work in the large towns such as Dublin and Belfast it is sufficient to say that satisfactory results have been absent. The local sanitary authorities have, in fact, up to within the last year or two, ignored the whole question. No attempt has been made to erect sanatoria or to disinfect houses where tubercle has occurred, and nothing has been done to educate the people. The Local Government Board, which exercises a general supervision over the local sanitary authorities, has occasionally issued a circular on the subject of tuberculosis, but has never seriously attempted to make its advice effective. It would seem, however, as if a general awakening might be at hand. Within the past two years the public has taken some interest in the matter, and schemes are on foot in many counties for the erection of sanatoria. The local bodies are beginning to discuss practical measures, and discussion is a means of education. Popular lectures have been delivered in many centres, and instruction in hygiene is given to teachers. Since her arrival in Ireland, Her Excellency the Countess of Aberdeen has shown a marked interest in the subject, and, as our readers are aware, her interest has borne fruit in the Tuberculosis Exhibition at present open in Dublin. Moreover, the Local Government Board has declared that it is alive to the importance of the subject, and has devoted two pages to the question in its Annual Report. At the present moment the Tuberculosis Exhibition has aroused much interest, and the series of lectures organised in connection therewith have been the means of interesting and educating large numbers of the general public. What is requisite is to make use of this general interest before it wanes. It is necessary to have a definite programme ready, and, fortunately, there need not be much dispute about the terms of it. The first thing necessary is to educate the people in the means to be adopted in every home to prevent the spread of the disease. The value of fresh air and cleanliness, and the need for proper precautions where the disease is present, must be impressed on every man, woman, and child in the country. In this work of education the chief, but by no means the entire, responsibility must rest with the members of the medical, clerical, and teaching professions. Along with this, steps must be taken to provide for those who are already diseased. Sanatoria, isolation hospitals, and dispensaries must be established where required, and it must not be forgotten that money spent in this direction is soundly invested, for the capital of a nation is its healthy sons and daughters. Finally, the housing problem must be settled. We believe that, given determination to deal with it on such lines, the tuberculosis problem in Ireland is capable of arrangement, and the next generation should be in a fair way for settlement.

THE BRISTOL INFIRMARY DEADLOCK.

The deadlock at the Bristol Royal Infirmary, much as it is to be regretted from many points of view, nevertheless brings to the front various points of vital importance to the future welfare of medical charities in the United Kingdom. It is too much the fashion of the governing boards of such institutions to override the deliberate and expressed wishes of their medical staffs. After all, the services of the latter are purely honorary, and they are plainly entitled to some say in matters which intimately concern the ordering of their private lives. In the present controversy the governors of the Royal Infirmary were requested to attend the half-yearly meeting of the Board to vote on the proposed alteration to Rule 36, which laid down that no member of the staff should hold any further appointment other than in the local University or Medical School, or engage in other than consultant or special practice. We are informed on good authority that when this proposal was discussed in committee it was thought that the Faculty had given their approval; and so they had, with the following addendum :—"This rule, as it stands, seems unfeasable; we assume that certain exceptions are contemplated." As a matter of fact, that opinion was not before the Committee, and the exceptions have never been formulated or discussed. The reason for this latter curious fact is, we learn, that the President would not permit discussion. Accordingly, the bald rule was passed, although in obvious opposition to the medical staff. The *fons et origo* of the whole affair appears to lie in the determined resolution of a strong President to carry the rules. That gentleman, Sir George White, has already done a great deal for the Infirmary, and in the event of his present wishes being carried into effect, we understand will do a great deal more. It is clear, however, that the rule cannot be passed without the resignation of the medical staff. If Sir George White is prepared to face that contingency he is assuming a position of very grave responsibility. Approaching this matter from a professional point of view, we own that our sympathies lie wholly with the staff. We feel that they are asserting the ordinary rights of medical men who hold these honorary posts, and we may congratulate ourselves that the safeguarding of important ethical principles is fortunately upon this occasion vested in strong and able hands. If once it be conceded that the benefactor of a medical charity is entitled to play fast and loose with the private lives of the honorary medical staff then the prestige of such institutions will indeed receive a deadly blow. The medical profession is long-suffering and anxious to work in harmony with all philanthropic schemes. It is too much, however, to ask them to sacrifice their independence of thought and action at the bidding of autocratic presidents and boards. The ultimate decision lies in the hands of the governors, and we shall be disappointed if the latter do not prefer to uphold the legitimate and strictly reasonable wishes of the medical staff, even should there be a prospect of some temporary loss of material prosperity to an ancient institution.

CURRENT TOPICS.

The Irish Local Government Board and Consultants' Fees.

The Irish Local Government Board is a body which, as a rule, endeavours to do its best under difficult circumstances, and which undoubtedly gets numerous opportunities of showing its powers. Indeed, so numerous are these opportunities that we should have thought it unnecessary for the Board to go out of its way to create difficulties. Yet, apparently, such is its desire. The latest task which this voluntary Sisyphus has set itself is that of regulating the fees charged by consultants over whose actions they have no more control than have we over the salaries of the eminent gentlemen who comprise the Board. On a recent occasion, a well-known Dublin Hospital surgeon was called into consultation by the medical officer of a country workhouse hospital to see a patient who had received a compound fracture of the skull and severe injury to the spine, the result of a fall off a bicycle. In order to give the patient the benefit of his advice the consultant had to travel some twenty miles, and was away from his practice for four hours. As a result of the united efforts of the two medical men the life of the patient was saved. The consultant named five guineas as his fee, and the amount was ordered for payment by the local Board of Guardians. Such Boards, even in Ireland, contain cranks among their number, and the particular crank in this case was a gentleman whose views expressed themselves in the dicta that five guineas were too much to pay any doctor, and that their medical officer had no right to summon a consultant from Dublin when he could have called in one of his local colleagues. With this gentleman's views it is unnecessary to deal. It is probable that if he required medical advice himself he would seek what he considered was the best advice available, and it is obvious that he is determined that the poor under his charge shall not similarly benefit, since it is impossible for any medical man to be a good general practitioner and at the same time to have the intimate special knowledge which is possessed by a consultant, if he is one in more than name. The crank accordingly wrote to the Local Government Board to protest against the payment of the consultant's fees. The Local Government Board in turn wrote to the local Board, and in the letter, in which it asked for information regarding the case—a very proper request—it stated "that five guineas certainly appeared to be an unusually high sum to pay a doctor for consultation fee." Sisyphus must roll his stone up the hill; it is for that he is paid, but why, for the sake of the plaudits of the onlookers, should he increase his difficulties by occasionally pushing it in the opposite direction? The Local Government Board has no power whatsoever over the fee charged by a consultant, brought in as was the consultant in the present case, and why it should go so far out of its way as to make an incorrect and unjustifiable statement about a matter over which it has no control is one of those often-occurring puzzles with which "Boards" like to perplex the public. Much as we should like to support the Irish Local Government Board in a good cause, when by its actions it departs so far from its proper sphere as to try to lay down the fees to be charged by medical men over whom it has no control, especially when those fees are below rather than above the average, and when it indirectly endeavours to inculcate into the minds of local guardians that expert advice is a luxury for the rich, and is not a necessity for the poor, we cannot but feel that "quem Deus vult perdere, prius . . ."

School Board Medical Certificates.

THE question of payment for School Board certificates deserves the deep and earnest attention of all bodies concerned in protecting the interests of medical men. At present medical practitioners for the most part sign these documents free of charge, either in hospital or private practice, and thus add to the already swollen volume of gratuitous service conferred upon the community. As usual, the organisation that demands the certificates makes no provision for remuneration of the responsible professional man who grants the document. Obviously, the majority of parents are unable to pay fees for certificates. Why should not the State pay for documents which it finds to be vital to the safe and proper conduct of its schools? What possible excuse can there be for declining to pay? While it is hard to find an answer to that question, it is easy enough, on the other hand, to imagine that the unbusinesslike medical profession has never asked collectively to be paid for its services. If the medical staff of one dictrict or of one hospital decline to issue unpaid certificates, they are at once stale-mated by neighbours who are ready to continue the gratuitous service. It seems more than likely that if the medical profession united and took a firm ground upon the matter, that the School Board authorities throughout the kingdom would be reduced to reason within a short period of time. The Colchester medical men intend to try, for they have notified the Education Committee of the town that they will in future refuse to sign School Board certificates except at a fee of half-a-crown apiece. The Committee some time ago offered eighteenpence. This result shows what may be done with a little courage and enterprise.

The Administration of Anæsthetics for Unqualified "Dentists."

WE have received a letter from the secretary of the Irish Branch of the British Dental Association calling our attention to the efforts of the Association to stop the administration of anæsthetics for bogus "dentists" by medical men. We are aware that such a practice exists, but we venture to think that it is not of such important dimensions as the Association seems to imagine. Still, even if only isolated cases occur, the fact remains that it is not only forbidden by the General Medical Council, and grossly unfair to the dental profession, but that it is also a short-sighted policy from the point of view of the medical profession itself. How can the latter profession hope to obtain the support of the public in its struggle against quackery and unlicensed competition, if it directly or indirectly supports similar competition in another and allied profession? The excuse which we have heard offered, that the "dentist" for whom the anæsthetic has been administered is capable of doing his work, or is a highly respectable individual, has nothing to do with the case. If such is a true description of him, then it is a great loss to himself and to the public that he has never become a registered dentist. Medical men cannot take these points into consideration, but, rather, are bound by every consideration of honour and of professional interest to refuse to have any professional dealings with unregistered dental practitioners. We are glad to see that the Irish Branch has brought the matter before the General Medical Council, and that the latter body has communicated with alleged offenders. We trust that the warning thus given by the Medical Council will be sufficient, as it would be a most unpleasant occurrence if more serious action had to be taken. *En passant* we take the opportunity of again pointing out to correspondents that if they wish their communications attended to, they must send them, in the case of Great Britain, to the London office, or in the case of Ireland, to the Dublin office.

Medical Examination of Engine-Drivers.

OF all callings in the world, that of an engine-driver demands the most perfect alertness, both of mind and body. A moment's delay in perception, a moment's indecision or inattention, and a hundred lives may be hurled into eternity. Under such circumstances it is a standing monument to the listless apathy of the British public that they do not insist upon a reasonable limit for the hours of duty of railwaymen. Hardly less amazing is the fact that they have not long ago made it compulsory for the railway companies to maintain a constant medical supervision of enginemen and guards. Only last week an inquest held at Paddington revealed the fact that an engine-driver was affected with locomotor-ataxy, and that he had returned to work shortly after an attack of broncho-pneumonia. Medically speaking, to place a man suffering from locomotor-ataxy in charge of a train would be little short of criminal recklessness. On general grounds, we maintain that every driver, stoker, guard, and signalman should be examined medically, say, once every three months. Nor should he be permitted under any circumstances to resume his duties after an attack of illness without a special medical certificate of his fitness. In the face of many serious railway accidents of late it is to be hoped that the House of Commons will enquire into the simple but highly important matter of the periodical medical inspection of railwaymen.

Medical Heroism.

The institution of a special decoration for heroism amongst medical men might be worth some little attention of the powers that govern such matters. Certainly there would be no difficulty in finding worthy recipients of any such distinction from time to time amongst members of our profession. The latest reported instance of self-devotion of this kind comes from Glossop, where a well-known Belfast physician, Dr. Thomas Waddell, has once more performed the now familiar feat of sucking a tracheotomy tube free of diphtheritic membrane. The details have a familiar ring. The patient was the only child of a poor woman, and the instant clearing of the tube was a matter of life or death. The child got well, and his rescuer contracted the disease, from which we are glad to say he has since recovered. From a philosophical point of view it may be argued that Dr. Waddell was not justified in risking his own valuable life for the sake of that of an infant in which the value was merely potential. Apart from intellectual analysis, however, we are proud to claim him as a fellow member of the profession in which unswerving self-sacrifice and obedience to the call of duty constitute the supreme law.

Norman Kerr Memorial Lecture.

The problem of inebriety was dealt with by Dr. Welsh Branthwaite in his second Norman Kerr Memorial Lecture in an extremely interesting and useful fashion, and it would be good if this puzzling question were always handled in the same detached and unbiassed fashion. Dr. Branthwaite shows that the inebriate, properly so called, is a person who cannot live soberly; that, indeed, is his definition of an inebriate, and that in a large proportion of cases he is suffering from obvious mental defect. Of persons confined in inebriate institutions he finds no fewer than 62 per cent. are actually mentally defective, and he adds that if he had his own way he would class practically the whole number as lacking mental competence, but he fears to do so lest he should be taken for a special pleader. A fair proportion of persons committed to retreats by magistrates are actually certifiably insane, 15 per cent. indeed, and the majority of these have become alcoholic because of their tendency to insanity, and not insane as the result of alcoholism. In the more or less defective group—constituting 46 per cent. of the whole—nearly all the patients show definite stigmata of degeneration, in cranial conformation, general physique, or conduct. The mental symptoms exhibited by such include impaired development of the moral sense, imperfect control over impulse, and defective judgment. From a practical point of view all these inebriates are hopeless as regards cure. Of the 37 per cent. of "average mental capacity" Dr. Branthwaite says that by no means are all these improvable, for though not actually and demonstrably defective, they are all of persons of impulse and dwarfed moral responsibility, although they have some qualities which may be appealed to. In the redeemable class Dr. Branthwaite has found that moral influences, such as religious emotion, the impress of a strong character, and even faith cures, are at times successful, whilst he speaks hopefully of the reinforcing value of medicinal treatment, and, naturally, of hygienic measures, for the reformed drunkard good social environment and total abstinence are imperative.

Quarterly Journal of Medicine.

We have a new medical contemporary to welcome, namely, the "Quarterly Journal of Medicine," and we can honestly say that if it keeps up to the standard of its first number, even if it does not have a large circulation, it will have a decided influence for good in stimulating authors to produce papers of equal merit. Although not specificially stated, we gather that the new "Quarterly" is practically the journal of the new Association of Physicians of Great Britain and Ireland, which held its first meeting last May; at all events, the papers in the number before us are those communicated to that meeting. The editors are six in number: Professor Osler, Dr. Rose Bradford, Dr. Garrod, Dr. Hale White, Dr. Hutchinson, and Dr. Rolleston, and as they have the assistance of twenty-five assistant editors, we judge there will not be much fear of failure. The Quarterly is beautifully printed on really good paper, with plates and diagrams of great excellence, but considering the cost of each number is 8s. 6d., that is not to be wondered at. Naturally, in a journal of this type the contributions are mostly records of purely scientific work or of rare individual cases, but they are all very interesting, and of a high level of merit. We have been much interested ourselves in a paper of Professor Osler's "On Multiple Hereditary Telangiectases, with Recurring Hæmorrhages," which describes a condition not infrequently met with, and up to the present very inadequately described, but perhaps the most important contribution is that by Dr. E. I. Spriggs "On the Excretion of Creatinin and Uric Acid in some Diseases involving the Muscles." We wish our contemporary all the success it so well deserves.

PERSONAL.

Mr. C. T. Street has been elected President of the Wigan Medical Society for the coming year.

Dr. R. J. Probyn-Williams, President of the Society of Anæsthetics, took the chair at the annual dinner of that body on October 18th.

Dr. S. J. Gee presided on October 22nd over the first meeting of the Medical Section of the Royal Society of Medicine.

Professor Howard Marsh has been elected Master of Downing College, Cambridge, in succession to Dr. Alexander Hill, resigned.

Mr. J. Howard Mummery gave the inaugural address at the meeting of the Odontological Section of the Royal Society of Medicine on Monday last.

Dr. J. Ritchie has been appointed an examiner in Pathology at Cambridge University, and Professor R. Stockman an examiner in Pharmacology.

Mr. A. J. Balfour, M.P., performed the inauguration ceremony of the new building in connection with the Royal Victoria Hospital for Consumption, Edinburgh, on Friday last. The hospital was founded in 1887 as a memorial of Queen Victoria's Jubilee.

A CLINICAL LECTURE
ON
THE PREVENTION OF FEVER IN THE PUERPERIUM. (a)

By H. OLIPHANT NICHOLSON, M.D., F.R.C.P.E.,

Assistant Physician to the Royal Maternity Hospital; Late Obstetric Physician to the New Town Dispensary, Edinburgh.

GENTLEMEN,—In the near future it will fall to the lot of most of you to engage in general practice, and in this sphere of work midwifery will claim a large share of your attention. Midwifery work not only taxes the bodily strength severely, but to men of high-strung sensibility the anxiety associated with it is very great. When you have to undertake the entire responsibility of your midwifery cases you will worry especially over two things—hæmorrhage during the third stage of labour, and fever in the puerperium.

It is difficult for you to realise at present, working as you are in hospital practice and under supervision, the kind of anxiety that is occasioned from these two causes in the attendance upon labour cases. The constant fear of post-partum hæmorrhage makes midwifery work impossible for some men, and drives them into other branches of the profession. I am not going to speak about hæmorrhage to-day, but only wish to say that although serious flooding after labour is a terribly trying ordeal for the practitioner to pass through, and severely tests the strongest nerves, still it is not the right attitude to take up to admit that one is afraid to face it and deal with it. I do not think that any form of anxiety can be so intense as that experienced by the physician during the management of a dangerous post-partum hæmorrhage. It is then, gentlemen, that you will realise the heavy load of responsibility which you bear, when you see the woman who relied upon you to conduct her safely through her confinement lying exsanguine and possibly all but moribund. The terrible anxiety associated with such hæmorrhage is, however, of comparatively short duration, and I wish you particularly to remember that a fatal result is quite exceptional. In almost every case a competent, cool-headed man can control the bleeding.

The other source of worry in midwifery work is the occurrence of fever in the puerperium. You notice that I say fever in the puerperium, and not puerperal fever, and for this reason—that any rise of temperature in the early days of the puerperium will cause you anxiety. You cannot say precisely what is the significance of the raised temperature, and you will generally find yourself taking the worst possible view of the abnormal symptom. Fever in the puerperium, whatever its origin, if it is moderately high and lasting, will greatly disturb your peace of mind, and the anxiety occasioned by it will continue so long as the temperature is elevated.

When you realise how important it is, both as regards success in your practice and pleasure in your work, that you should have a practically afebrile puerperium after each labour, you will understand why I wish to take the earliest opportunity of discussing some of the measures whereby such results can be secured. My remarks relate to the safeguarding of your patient from fever in the puerperium which is due to septic infection. You cannot, of course, always control the other conditions which cause a rise of temperature at this period, but these are generally unimportant and harmless compared to true septicæmia.

While it is a well-established principle that antiseptic measures are absolutely essential in the practice of obstetrics as a means of preventing septicæmia, still, as regards details, the technique varies considerably in the hands of different practitioners. First let me impress this fact upon you, for it is an important one—namely, that the antiseptic treatment of a midwifery case is one thing, and that of a surgical case something quite different. Do you imagine that it is possible in routine practice, or even in a maternity hospital, to sterilise the external genital organs and vulvar skin of your patient as completely as you can the skin of the abdomen previous to an operation? It is quite impracticable, and even assuming that you can get these parts relatively aseptic, there is also this difference from a mere surgical procedure—that you have to keep everything in an aseptic condition for a week or ten days at the least, in order to avoid the introduction of infective material from without. You must remember also that your own responsibility for the antiseptic treatment of the patient terminates at the end of the labour; the nurse or the next-door neighbour undertakes to carry out similar precautions during the puerperium. And yet, gentlemen, it is the rule for things to go well. I am putting the matter before you in this way because I am bound to confess to you that the safety of the lying-in woman does not depend upon *real* surgical cleanliness on your part; if it did, the mortality from sepsis would be too appalling to think about. Practically speaking, something far short of this seems to be sufficient to enable one to obtain a normal puerperium even after the most complicated labour. Now, although you know that you cannot render your hands and the vulvar orifice of your patient surgically aseptic, please do not conclude that you can afford to neglect one little detail in the attempt to do so. You simply must not, or, sooner or later, disaster will certainly follow. No precautions which both you and the nurse take to prevent infection can be too elaborate, and the more systematic they are the better. In the present state of our knowledge it is criminal to conduct even a perfectly normal labour without the most careful preparation of the hands, and the proper disinfection of the vulva and vaginal entrance is of quite equal importance. Neglect to cleanse the vulva is unpardonable, and yet I do not advise you to shave it and scrub it, as the gynæcologist would do before performing vaginal hysterectomy. That is quite unnecessary, and if you attempt to carry out such thorough disinfection your midwifery list will never be a large one. Simply remember that the cleansing of the skin around the vulva by means of a strong antiseptic solution is absolutely essential if you hope to keep your patient free from septic infection.

At the best, as I have told you, neither your hands nor the vulvar parts will be surgically aseptic, but, with reasonable precautions, they are sufficiently clean to make it very unlikely that infective material will be introduced into the vagina and uterus during an ordinary examination, or in the course of any operative interference.

I do not wish you to run away with the idea that you can in this way keep the vagina free from micro-organisms, because you can never do so. You can keep it free from dangerous pus-producing organisms—streptococci and staphylococci—and that is all you need care about. Bacteria are always present upon the vulva and in the lower third of the vagina, and some of these organisms, if implanted in the uterus by the examining finger, are doubtless able to set up putrefactive changes if there is any material present suitable for bacterial growth. Fortunately, in the majority of cases, there is no suitable culture medium, and I want to particularly impress upon you that it is for this reason, and also because the normal vaginal secretions possess strong protective powers against bacteria, that the puerperal woman comparatively seldom goes septic. You must never flatter yourselves that the antiseptic precautions you have adopted—absolutely necessary as they are—deserve all the credit in the successful recovery of your patient; the normal protective mechanism against infection is an enormously important factor to take into account. A knowledge of this carries with it a warning against the use of the antiseptic vaginal douche. Before labour, such a proceeding is, in my opinion, almost always more likely to be a source of danger than a safeguard; and routine douching after labour, I sincerely trust, will soon be entirely abolished. It is positively dangerous, and is often the surest way to court disaster in the way of sepsis.

(a) A Lecture delivered at the Royal Maternity and Simpson Memorial Hospital, Edinburgh.

Safeguarding Against Septic Infection.

I shall describe to you what I regard as the best and simplest means of safeguarding the parturient woman from septic infection. The methods are simple in the extreme, and can be carried out in the poorest cottage in town or country.

All the methods commonly adopted for the protection of the lying-in woman from infection have one aim—they are all concerned with keeping bacteria out of the genital canal. Rigid precautions are therefore taken to prevent the introduction of infective material during vaginal examination and during operative interference. This is all very well, and is, of course, very important; but in my opinion too little attention has been given to the equally important matter of making sure that the involution of the uterus goes on normally in the puerperium. It is admitted by everybody that there is a very close connection between a relaxed enlarged uterus and the occurrence of septic trouble, and the very best safeguard against this is that the uterus should remain well contracted during the whole course of the puerperium. I invariably adopt measures to secure efficient uterine involution, and, in the prophylaxis of puerperal morbidity, I have no doubt in my own mind how important this part of the treatment is.

To come to practical details, gentlemen, let me first tell you how to avoid introducing infective material into your patient's genital tract.

You can do this, as I have already told you, by the proper disinfection of your hands and of the skin around the vulvar orifice, and you require nothing more than a good nail brush, soap, and some reliable antiseptic. In the poorest house you can always obtain soap and a couple of basins of hot water. Take off your coat, turn up the sleeves of your shirt, and, if possible, put on a long sterilisable overall. Then scrub your hands, arms, and nails very thoroughly in soap and hot water. This means that the washing process lasts for nearly five minutes, and if you can get two changes of water, so much the better. When the nails are softened, trim them and clean them, if necessary, before soaking the hands in the antiseptic solution. Next comes the question of what antiseptic you are going to employ, and let me advise you very strongly to stick always to corrosive sublimate. You may use either the perchloride or the biniodide of mercury, and, in the form of compressed tablets, one can readily make a solution of the necessary strength. Personally I always use perchloride tablets, one of which, dissolved in an imperial pint of hot water, makes a solution of 1 in 1,000 strength. Here let me ask you to remember two things: first, that perchloride of mercury is far and away the best and most reliable antiseptic to use for the hands and for the patient's vulva; and, secondly, that 1 in 1,000 is the weakest solution you can trust for such disinfection. Do not believe anyone who tells you that some other antiseptic is equally safe for the protection of your patient, or that a 1 in 1,000 strength is unnecessarily strong. After a preliminary use of the perchloride solution for your hands and for the patient's external parts, you may conduct the labour, if you wish, with a solution of lysol (1 in 150 of water); but if you take my advice you will never omit to use perchloride in the first instance.

After the hands have been thoroughly washed, the soap is removed by rinsing in clean water; a towel should not be used. Then you proceed immediately to disinfect your hands in a basin of hot perchloride solution of 1 in 1,000 strength. Put a pledget of absorbent wool into the solution, and bathe the arms thoroughly, and again use a brush for the nails. Make this disinfection process last about three minutes.

The hands are now ready to make the vaginal examination, and they must not come in contact with anything until that time arrives; the next thing is to be equally careful about the disinfection of the vulvar skin and vaginal entrance.

In dispensary practice, where no nurse is present at the time of labour, I teach my students to carry out the following method, which, imperfect as it may appear to you, is, nevertheless, to be relied on, when carried out in conjunction with the after-treatment I recommend, to give you a complete immunity from septic infection. First, it is important to get the patient into the proper position in bed, so that the vulva may be efficiently cleansed, and the vaginal examination easily carried out. The left lateral position is the best, and the patient is placed well across the mattress, so that her back is nearly parallel with the top of the bed. You then carry the basin containing the perchloride solution over to the bedside, and, with a pledget of wool soaked in the antiseptic, swab the skin around the vulva. Then separate the labia and gently scrub the external organs as well. This being done, the patient may be safely examined, and, in my opinion, examined as often as you wish, if you continue to swab the parts from time to time, and keep your hands soaked in perchloride or lysol solution. I am not one of those who advocate one or two vaginal examinations only during the course of labour. I believe no increased risk is incurred from frequent and, if necessary, prolonged examinations, if due care is exercised in maintaining the antisepsis of the hands and external parts. You may use a lubricant if you wish, and it is pleasanter for the patient if you do so. If you use vaseline it is a good plan, after smearing it on the fingers, to immerse the hand in the perchloride solution before you examine.

So much, then, gentlemen, for the first part of your preventive treatment of puerperal infection—namely, keeping the genital tract free from pathogenic bacteria. But that is by no means all. You have next to take care that trouble does not arise from pieces of blood-clot, placenta, or membranes, which may be left in the uterus and vagina, and which, for some reason, do not remain aseptic until they are got rid of in the lochial discharge. Otherwise the temperature will rise in the puerperium.

This is why the second part of the treatment, namely,

Assisting and Maintaining the Involution of the Uterus,

is so important. Many practitioners, however, who are sufficiently careful of their hands and of the patient's vulva neglect this side of the question, and, by quite unnecessary interference, set things wrong when they would otherwise go right. I refer to the common practice of douching, not only immediately after labour, but also during the puerperium. Personally, gentlemen, during the last ten years of my practice, at any rate, no patient for whom I have been responsible has had her uterus washed out, no matter how complicated the labour may have been. The whole principle of the thing is wrong, and while a single washing out of the uterus, after having had one's hands or instruments inside, may do no actual harm, it cannot possibly do good in the way of killing organisms. Routine douching of the vagina, especially in the early days of the puerperium, may be a source of much harm, and it is only when the lochia become highly offensive that I sometimes advise it.

I wish now to tell you how you can best carry out the second part of the prophylactic treatment against sepsis; how you can guard against the infection of retained clot and membranes, and assist the uterus to expel these safely.

When the placenta leaves the uterus and is expelled out of the vagina, it sweeps the whole genital tract clean. It may be assumed that any pieces of clot and membrane left behind are aseptic, and that they will be safely got rid of if the uterine action is efficient. Hence, from this moment, it is most important to keep the tract closed, and thus avoid the infection of anything left inside. That is why I caution you so strongly against reopening the vagina with the nozzle of your douching apparatus. If you can assist the uterus to involute rapidly and well, and expel anything retained in its cavity, it must be admitted that there is greater safety for the lying-in woman. I have now ample evidence that this can be accomplished in a precise and definite manner.

The uterus can quite properly be compared to the heart; both are hollow muscular organs, and both are endowed with the power of contracting rhythmically. The uterus, like the heart, goes into a systole, and this is followed by a diastolic period. During its systole the uterus contracts; during diastole it is retracted. I want to remind you that the uterus begins to contract and relax from an early period of pregnancy—painless contractions; that it does so more actively during the period of labour, when the contractions become painful, and that it continues to contract during the puerperium. The systoles of the uterus are few and far between, but it is a perfectly well-established fact that certain drugs can definitely increase and prolong the contractions, and, just as in the case of the heart, improve the general tone of the organ. Digitalis is the principal remedy one uses for the heart, and it acts beautifully on the uterus during the puerperium, keeps it firmly contracted, and helps it to get rid of anything retained in its cavity.

Acting on this principle, gentlemen, I order a "post-partum" pill for every patient who comes under my care. The pill I usually prescribe contains pulv. digitalis, ½ gr.; ergotin and quin. sulph., of each a 1½ gr.; and ext. nucis vom., ¼ gr.; and, in most cases, it is given thrice daily for the first ten days of the puerperium. Sometimes it is given every four hours at first, if the uterus is larger than it should be, while in other cases one pill night and morning is sufficient. This pill was given from the first day of the puerperium, to nearly every one of the thousand patients who were attended from the New Town Dispensary during the five years that I acted as obstetric physician, and with most gratifying results as regards the puerperal morbidity. There was no maternal death from any cause, and no case developed septic complications which caused us more than quite temporary anxiety. When one has no death in over 1,000 cases of labour in this class of practice, there is, of course, some element of luck, because eclampsia and hæmorrhages may, at any time, claim a victim. And in this series of cases there was more than the average proportion of difficult and dangerous labours. But when one can keep such a large number of cases, treated under far from favourable conditions, practically free from septic infection, some credit must be given to the preventive measures adopted. None of the cases treated by this pill had secondary hæmorrhage, though frequently large pieces of membrane and bits of placenta were expelled from the uterus during the puerperium.

Should the temperature rise to 102° or more, and the pulse rate simultaneously quicken, as sometimes happens about the third or fourth day or later, I order, in addition to the pill, powders containing 5 grains of quinine with 10 grains of salicylate of soda. Such a powder is given every six hours for three or four doses, and this often leads to the temperature falling, and the puerperium goes on normally again. Certain objections have been raised to the use of this "post-partum" pill, but they are mainly theoretical, not practical. It has been said that when the temperature is raised in the puerperium, digitalis, by slowing the pulse, will mislead one into thinking that there is not much wrong. This is quite a mistaken idea, because, if fever is present, digitalis will have practically no effect in slowing the heart's action. It has also been said that the quinine and nux vomica are excreted by the mammary gland, and that the baby will refuse the breast because the milk tastes bitter. This is likewise a purely theoretical objection.

You may take it from me, gentlemen, that by the routine use of this pill in the puerperium you will greatly lessen your anxiety over the recovery of your cases. If you have been, in the first place, thoroughly careful in the details of your disinfection, you will be agreeably surprised to find even your most unlikely cases go through the puerperium without the development of any untoward symptom.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Thomas Sinclair, M.D, F.R.C.S. Eng., Professor of Surgery in Queen's College, and Surgeon to the Royal Victoria Hospital, Belfast. Subject: "A Case of Traumatic Epilepsy Treated by Operation."*

ORIGINAL PAPERS.

A PLEA FOR THE WIDER RECOGNITION OF BUDIN'S METHOD OF FEEDING INFANTS ON STERILISED WHOLE MILK.

By M. P. KERRAWALLA, M.D. (BRUX.), L.R.C.P. and S.E., L.M.R.C.P.I.

Resident Medical Officer to the Brighton and Hove Hospital for Women and Lying-in Institution.

AT the present time, when so much is written and said about the prevalent high rate of infant mortality, want of efficiency and safety of milk supply, I beg to urge a wider adoption of the plan of bringing up infants on sterilised whole milk as a contributing factor towards the amelioration of the above conditions. Apart from the deplorable tendency among the present-day mothers of trusting more and more to artificial feeding, under certain conditions breast feeding is impracticable, and in such cases the above method would go far towards lessening the disadvantages and evils of artificial feeding.

According to Dr. G. F. Still (*a*), 96 per cent. of the cases of infantile diarrhœa investigated by him at the Children's Hospital were hand-fed. He also points out that condensed milk is particularly dangerous, and the child who is taking it runs a special risk of summer diarrhœa. He found that of the fatal cases of diarrhœa, 25.8 per cent. had been fed upon condensed milk.

In the unfortunate absence of any proper State supervision of milk supply, the milk has to be rendered innocuous, but in a manner that does not prejudice its nutritive value.

Boiling, though it kills germs, alters the nutritive value of milk, and is therefore unsuitable for very young infants.

Pasteurisation requires a rather complicated apparatus, and if rapidly done, though it retards the growth of germs, it does not destroy them.

Sterilisation of milk is attained by surrounding the vessel containing milk with water which is raised to boiling point and kept so for 40 minutes. It is admirably achieved by means of any of the sterilisers on the market, notably that of Soxhlet, in which the quantity required for each feed is separately dealt with. But the method is capable of being carried out even without the aid of any special apparatus. The plan, as successfully tried by me in the case of my poorer patients, was to instruct the mother as to the great importance of cleanliness and procuring milk from a reliable source, and then advise her to put the milk required for each feed in a separate small glass bottle (or, if that was too troublesome, the quantity for 24 hours or part of it), and put this bottle immersed three-quarters in a saucepan of water, the water being subsequently raised to boiling point and kept so for 40 minutes.

The milk is slightly warmed before giving it to the infant, and no addition of sugar or cream is required.

The plan, as originally suggested by Professor Budin, of Paris, has been carried out by him and other Continental authorities for many years with gratifying results. In this country there exists a great prejudice against sterilisation, as it is thought to lead to scurvy; but Budin and other authorities who have reared a very large number of infants, have failed to record even a single case of scurvy resulting from the use of sterilised milk.

Professor Kenwood, in a paper (*b*) read before the

(*a*) MEDICAL PRESS AND CIRCULAR, August 28th, 1907.

(*b*) MEDICAL PRESS AND CIRCULAR, August 21st, 1907.

Section of State Medicine at the last annual meeting of the British Medical Association, makes the following remarks:—"In America, Denmark, and France, each with an extensive experience covering many years, the verdict is favourable to sterilised milk. Dr. Variot, whose experience is unique, since his feeding experiments at the "Goutte de Lait" at Belleville relate to over 3,000 healthy as well as unhealthy children who were closely observed by him for many months, has seen nothing of infantile scurvy resulting from the use of sterilised milk. The facts collected from the experience of other such institutions abroad, and from the Consultations des Nourrissons in France, are further testimony to the almost absolute harmlessness of sterilised milk. On all sides the general experience is that extremely little scurvy results from the use of sterilised milk, and the late Professor Budin, whose consultations are now established all over France, and were first started in 1892, wrote to me under date April 6th, 1906, that as the outcome of his wide experience he had not seen a single case of scurvy resulting from the use of sterilised milk."

By using the milk previously sterilised, Budin and other authorities claim that they never saw in their patients, rickets, eczema, abdominal distension, dyspepsia, tuberculosis, scurvy or diarrhœa. By sterilisation the milk itself is submitted to a temperature of about 180° F., which, though enough to destroy germs, does not lead to any detriment in its nutritive value.

As regards the use of cow's milk undiluted from birth, I cannot do better than quote the following from Dr. Maloni's translation of Budin's work, of which I have availed myself freely. Should cow's milk be given undiluted?

It is generally supposed to be harmful to infants, owing to the excess of casein it contains, compared with human milk. To counteract this defect, great quantities of water are usually added to the milk, the dilution varying with the age. But casein is not the sole constituent of milk. It also contains sugar, butter, and salts, all of which materially contribute to the value of milk as a food. Diluted cow's milk is generally deficient in these substances, and therefore forms but a poor substitute for a mother's milk. To obtain sufficient nourishment on this attenuated diet, infants are obliged to absorb great quantities of fluid, which causes them to pass a large amount of urine. They are almost always crying from hunger, whereas infants on undiluted milk wait contentedly for their next meal.

It is alleged that casein of cow's milk forms large clots in the stomach, and gives rise to digestive troubles. This is obviated if the milk is heated in a steriliser at a temperature of about 100° C.

"According to my experiments in vitro," says Chavane, "the clot of milk thus sterilised offers no resistance or sense of elasticity to the finger on pressure. It yields like a thick fluid, such as cream, and on microscopical examination, although the fat globules are not appreciably altered, the particles of casein are found to be smaller and more homogeneous. It differs from the fine clot of human milk. It is distinct from that obtained from asses' milk, but it is quite comparable with the latter as regards the size of the casein particles. Obviously this sterilisation below boiling point—*i.e.*, heating to 100° C.—modifies the casein so as to effect the state of sub-division of the clot, and also the molecular structure of the particles. This probably explains why milk thus sterilised is more easy to digest than either fresh or boiled milk.

Sterilisation is greatly simplified by the use of undiluted milk. It is a complicated process when dilution has first to be performed according to the infant's age. When the same milk is dispensed to infants of all ages, the mother's duties are made easy, and the work greatly facilitated."

Lazard says:—"Infants, who are, after all, the best test of the quality of the milk, support sterilised milk admirably. I recommend it undiluted. Experience has taught its great value, for not only is it easily tolerated by healthy infants, but it is also the best remedy for diarrhœa in certain cases, and has saved marasmic cases veritably from the jaws of death."

Just as all infants do not thrive even on breast feeding, so some infants during the first month or so will not thrive on whole milk. In such cases, and in the case of weaklings and premature babies, Budin gives the milk, not diluted, but peptonised. He recommends pepsin in the form of small scales, a small amount of which (a pinch to a salt-spoonful) is given in water before meals. In some cases the addition of water, one-fourth the bulk of milk, added before sterilisation will be found efficacious.

The number of feeds in 24 hours is the same as in the case of undiluted milk, although a slightly less amount is required. In every case it is best to be guided by the condition and progress of the infant. By this method the infant takes less fluid, which in itself is an advantage, puts on weight more rapidly, and by reason of its leaving a greater residue in the alimentary tract, ensures regular action of the bowels. I can bear out these facts by personal experience. The obvious advantages of a method which brings about freedom of milk from germs, and obviates the necessity of handling it for the purpose of dilution and addition of cream and sugar, will not fail to appeal to those who are conversant with the drawbacks as regards these points in the poorer classes of community where the nature of these articles hardly inspires confidence as to their quality or purity.

The plan has been successfully employed at the Rotunda Hospital, Dublin, by its present Master, Dr. Tweedy, who in a letter on the subject to me states that during the interval of feeds the infant should be given as much water as it can take.

Personally, I have found the administration of a teaspoonful of olive oil night and morning a great help. According to Holt, one gets scurvy in every form of feeding. It is obviously the poor quality of milk which gives rise to the disease, and therefore the risk of it is greater in diluted than in undiluted milk.

During my connection with the Brighton Lying-In Institution, I tried the method in several cases, and in every case it gave me entire satisfaction. Even the nurses and mothers who at first regarded the plan in the light of a novel experiment did not fail to be impressed with the progress and well-being of the infant.

I have selected the following two cases to illustrate some of the remarks I have made above:—

(*a*) *Baby D.*—Weight at birth, 7 lbs. It was fed from birth on sterilised whole cow's milk, with dr. 1 of olive oil night and morning:—

1st	week	fed on	oz. i	2	hourly	weight	at the	end of	week	7¼ lbs.
2nd	,,	,,	oz. ii	2	,,	,,	,,	,,		7¾ lbs.
3rd	,,	,,	oz. iii	2	,,	,,	,,	,,		8¼ lbs.
4th	,,	,,	oz. iv	2	,,	,,	,,	,,		8¾ lbs.
6th	,,	,,	oz. vi	3	,,	,,	,,	,,		9½ lbs.
12th	,,	,,	oz. xii	3	,,	,,	,,	,,		14 lbs.

The child never suffered from sickness, diarrhœa, or any other trouble.

(*b*) *Baby P.*—Premature 7½ months baby. Weight at birth, 6 lbs. It was brought for advice when six weeks old, being very restless and irritable; weighed 6 lbs., and was suffering from abdominal distention and sickness. On inquiry it was found that the mother was feeding it on condensed milk, because she said she could not afford cream to dilute cow's milk. She, however, consented to try feeding it on sterilised cow's milk (undiluted), as it needed no outlay for purchasing cream. At the end of a week's trial, the baby looked better in every way, slept well, and had gained a little in weight. For twelve subsequent weeks it gained weight at the rate of half a pound a week.

The ease with which the method can be carried out, coupled with the immediate and remote advantages it holds out over other methods, will not, I feel sure, fail to impress anyone on a trial of it.

HÆMORRHAGIC RASHES. (*a*)

By GEORGE PERNET.

Assistant to Skin Department, University College Hospital, London.

(Concluded from our last issue.)

An important group of toxic purpuric rashes due to drugs must now be touched upon [15]. A number of drugs have been from time to time accused in this way, the chief culprits being iodide of potassium, quinine, antipyrin, chloral, copaiba and mercury. In

---

(*a*) A Paper read before the West London Medico-Chirur Society, 1907.

such instances the general condition of the patients has usually left something to be desired, either in the way of faulty renal elimination or cardiac disease, or the existence of other toxic conditions of organism at the time. Iodide of potassium as a toxic agent of this kind appears to head the list. Thus in a man with a purpuric eruption, it was found he had been taking iodide of potassium. He had a diastolic murmur and a cloud of albumin in the urine; moreover, there was some evidence of alcoholism. In a case of advanced nodular leprosy I had had under observation, and notwithstanding my warning that iodide of potassium should not be administered, the drug was ordered under the quite erroneous idea the case was one of syphilis after all; the result was a purpuric eruption about the legs. Lepers are specially susceptible to ordinary doses of potassium iodide, and this fact was made use of by Danielssen, of Bergen, as a test. In connection with this drug it should be borne in mind that it is the basis of advertised blood mixtures. Shepherd has recorded a case of purpuric eruption ending in gangrene, which was apparently caused by sodium salicylate [16]. Sandal-wood oil, administered under various names for gonorrhœa, has led to nephritis and cutaneous hæmorrhages, but it must be pointed out that the latter have occurred in the course of gonorrhœa apart from drugs, although doubts have been thrown on the gonococcus as the *fons et origo* [17].

In another group of cases, the acute pemphigus I have described as occurring in butchers, and arising from the infection of a wound, hæmorrhagic lesions and bullæ were noted in three of the eight cases I observed and collected [18]. In my case, Bulloch isolated a diplococcus corresponding to the microorganism described by Demme, a fact he has confirmed in another case very much like my own [19]. The complaint, a severe infection, is frequently fatal (seven out of nine in butchers).

The following hæmorrhagic vesicular eruption in an infant, one month old, was instructive. The skin condition commenced four days after birth, and when first seen the lesions, varying in size from a pin-head to a pea, were scattered about the body and limbs, including the soles and palms, but the child was well nourished and there was no evidence of syphilis. The eruption was totally different to that observed in congenital syphilis. At the *post mortem* a few days after, the right pleural cavity was found to be full of pus, demonstrating the toxic origin of the rash.

In herpes zoster some of the vesicles may be hæmorrhagic, evidence of the severity of the attack, and mixed up with the vesicular rash hæmorrhagic punctate groups without vesiculation may be present. In hæmophilics, cutaneous hæmorrhages may occur either spontaneously or after slight injuries. As you know, bleeders are generally of the male sex, though the "diathesis" is handed down mainly in the female line. Were it otherwise the females would run great risks at the establishment of the menses and also at parturition, but here again hæmophilia appears to be less severe in women when they are affected. Such hæmophilic hæmorrhages may be of medico-legal interest. In a case mentioned by Poore, the body of a boy, who had died after a flogging, was exhumed and numerous subcutaneous hæmorrhages were found. This was in 1856, when flogging and violent repressive measures were in fashion, the schoolmaster getting a long term of penal servitude. The case was probably an instance of hæmophilia [20].

In this connection I would call your attention to the importance of ecchymoses about the genitalia, breasts, face, lips, arms and legs of women and girls in cases of rape or attempted rape. Hoffman has pointed out that in some women there are pigmented areas at the upper inner parts of the thighs, that look very like ecchymoses or bruises eight or ten days old [21]. In investigating such cases, the characteristic signs of cutaneous and subcutaneous hæmorrhages must be borne in mind. It is also essential not to lose sight of the possibility of simulation. Fallot records the case of a girl who pretended she had been violated in a wood by some unknown man; in proof she showed some bluish spots on the internal surface of the thighs and posterior part of the back. The spots were round with a broken border and more discoloured at the edges than in the centre, two points suggestive of simulation, I may say. It was found the girl had been supplied with some thick blackish liquid which she had applied [22]. In the old days simulation of ecchymoses appears to have been frequent in the services. When produced by dry cupping or suction, the shape must be taken into account.

Again, spontaneous ecchymoses and skin hæmorrhages are stated to occur in the hysterical, and indeed to have been produced by suggestion. But although cases of this kind have been recorded by sceptical observers, it is well to keep an open mind on the subject. Such manifestations as bloody sweat and bleeding stigmata were at one time held to be a proof of possession by incubi, or as in the well-known Louise Lateau to be miraculous [23]. As to hæmorrhages under the nails apart from injuries, I may merely mention that they may accompany cutaneous hæmorrhages, or occur alone, as in hemiplegia, for instance [24].

I must now deal rapidly with the histology and mechanism of cutaneous hæmorrhages, together with their pathogenesis and ætiology [25]. On *à priori* grounds, diapedesis appeared at first to explain everything, but microscopical investigation showed this view applied to a few cases only, in the majority rupture of the vessels being present. On the other hand, Darier points out that almost all the vessels in purpura offer a remarkable integrity of aspect [26]. I would remind you of the two vascular networks of the skin, one superficial just below the papillæ of the skin and supplying the papillæ with capillaries (cutis vasculosa), the other subcutaneous, connected up with the former by vessels passing through the thickness of the cutis. According to Unna it is in connection with the deeper network that hæmorrhages most usually take place apparently, more rarely extending to the papillary network; more rarely still is hæmorrhage limited to the latter and the epidermis. The weak spot appears to be the point of entry of the hypodermic vessels in the cutis proper. In the microscopical investigation of hæmorrhages it is necessary to cut horizontal sections of the skin to get a clearer idea of the state of affairs, a method which enabled Unna to demonstrate more readily the seat of rupture in the vessels.

In the first place hæmorrhages may occur as a result of negative pressure, as in cupping. Here I should like to mention that, according to Leduc, the osmotic pressure of the blood is enormous, seven and a half atmospheres [27]. Another explanation was thrombosis, but the fact is that venous thrombosis may be present, with paresis of the arteries, as in erysipelas, without hæmorrhage necessarily occurring.

Again, bacterial emboli may be present in the capillaries without consecutive thrombosis, although the latter may occur. But it is beyond doubt that in purpuric eruptions bacillary emboli have been found.

In venous stagnation of the legs, ecchymoses and subsequent pigmentation may occur. I have seen ulcerations in varicose legs become distinctly hæmorrhagic, with a tendency to sloughing. But neither stagnation nor hypostatic hyperæmia in the veins of the leg leads necessarily to hæmorrhages in the skin. I need scarcely insist on the *post mortem* hypostatic discolouration and lividities sometimes taken for bruises by juries; they are not extravasations.

Naturally a point of importance in the subject we are considering is the condition of the vessel walls. A variety of changes have been put forward to explain hæmorrhages, such as molecular destruction, hyaline degeneration and so forth, to say nothing of defective formation. Again, it was natural to think of the toxic effects of poisons, bacterial and otherwise, on the walls of the cutaneous vessels. And here I should like to call your attention to the experiments which have been made with snake venom. Snake-bites are well known to produce hæmorrhages very rapidly. Snake-venom is a complex body, and its hæmolytic properties need not be insisted on here. But in addition to this property, Flexner and Noguchi have apparently shown that these hæmorrhages are due to the presence in venom of a cytotoxin, which has the power of dissolving endothelial cells, in other words an endotheliolysin [28]. This appears to me all the more important when taken in connection with the fact that the osmotic pressure of the blood is equivalent to seven and a half atmospheres, according to Leduc, a pressure which does not assert itself by morbid changes in ordinary circumstances. But when the vascular walls are damaged, the blood itself altered in various ways, and the vascular innervation interfered with, it is no wonder that rhexis should occur. I put this forward merely as a hypothesis, for I know but too well how many of our explanations need explaining. Things are not so simple as they seem, for in addition to the factors I have just alluded to, the cells of the organism are extremely sensitive to changes in osmotic pressure; thus in concentrated chloride of sodium solutions, the blood corpuscles lose their water and shrivel; in water and very dilute salt solutions they swell up and burst. It has been shown that all bodies are more or less radio-active, and moreover, it would appear that hæmoglobin acts like a catalytic ferment [29]. Hæmoglobin contains iron, which varies in quantity in different species. And here I would suggest that inorganic iron, which empirically sometimes gives good results in hæmorrhagic rashes, may act in a catalytic way, for according to Bunge, inorganic preparations of iron do not appear to be assimilated by the organism [30]. May not arsenic act in a similar manner, for arsenic undoubtedly does appear to act beneficially, in some purpuric conditions at any rate.

As far as the blood is concerned, the coagulability and the freezing-point (cryoscopy) are also elements in the problem, a very complex one indeed, as you will perceive, which will require much labour to elucidate, or even to approach elucidation.

Hæmolysis *in vitro*, at any rate, occurs as you know in a variety of circumstances, apart from snake-venom, as, for instance, by the addition of water, glucosides, foreign serum, and so forth [31]. On the other hand, Carnot and Desflandres have shown that if a rabbit be bled the blood is rapidly regenerated, but if during this regenerative process the serum be injected into a normal rabbit, a considerable increase of red corpuscles takes place in the latter, the number rising from about five millions, to eight, nine, and twelve millions on the three following days respectively. This regeneration appears to be due to a chemical substance which is destroyed at 55° and exists in small quantities under normal conditions, but in larger quantities after bleeding. This substance is present not only in the serum but also in the bone marrow [32]. Whether anything can be made out of this in the treatment of hæmorrhagic rashes the future will show.

As regards hæmolysis, may it not be that owing to the disintegration of the complex molecule of the hæmoglobin, a liberation of energy takes place with a bombardment of the walls of the blood-vessels by ions, electrons and other radiations? Leduc found that the experimental introduction of ions of calcic alkaline earths into the skin of animals produced blackish and ecchymotic lesions the next day, ultimately leading to ulceration with indurated base [33].

As an illustration of the severe attack on the blood in purpuric eruptions, I may mention a case of streptococcal morbus maculosus recorded by Heubner, a girl aged 9½, in whom the number of erythrocytes sank in a few days from 4,400,000 to 1,200,000, the white corpuscles numbering 9-10,000. Microscopically, there was neither poikilocytosis nor megaloblasts, but numerous normoblasts with pyknotic nuclei were present. The lymphocytes compared with the polynuclears were as 90 to 10. At the necropsy the bone-marrow was found to be raspberry-coloured and jelly-like, and almost entirely made up of mononuclear cells, with homogeneous protoplasm. Short streptococcal chains were also present between the cells. A pure streptococcal culture was obtained from the spleen [34]. The state of the bone-marrow and spleen have not, as far as I know, been systematically investigated in fatal cases of purpuric eruptions.

I have already referred to various micro-organisms found in cases of cutaneous hæmorrhages. But Kolb [35] and Finkelstein [36] have described what they consider to be the specific bacillus of idiopathic purpura, a bacillus which proved pathogenic when inoculated in animals. With regard to the pneumococcus, Klein has described the instructive case of a nurse who developed a purpuric rash over the lower part of the abdomen and inner part of the thighs. This rash was diagnosed clinically as hæmorrhagic variola, for the patient had had some intercourse with nurses who had been to the small-pox ships. The patient died. Sections of skin revealed numerous pneumococci and hæmorrhages in the cutis, but there was a subepidermal zone free from both, the epidermis being normal [37]. The "bathing-drawers" rash was certainly in favour of variola, but how account for the pneumococci? In a section of true hæmorrhagic small-pox figured by Klein the hæmorrhages were just below the epidermis, the latter showing cleavage on the way to vesiculation. To complicate matters further, Klein found in the nurse case micro-organisms that stained in a bi-polar manner, not dissimilar to those of *Bacillus pestis*, in addition to the diplococcus pneumoniæ.

I need not remind you of the fact that in plague cutaneous hæmorrhages may occur, especially in some epidemics.

I have referred to the influence of the nervous system, which is well exemplified in herpes zoster with hæmorrhages, depending as that eruptive condition does on a lesion of the posterior ganglion. When the toxic effects on the nervous system are intense, as is the case in severe variolous infection, a purpuric rash with a rapidly fatal *dénouement* may sometimes lead to variola being overlooked. Experimentally the destruction of the abdominal sympathetic ganglion in the frog has been followed by hæmorrhages in the lower limbs. At the necropsy in a case of purpura hæmorrhagica, Hale White [38] found acute inflammation of the semi-lunar and cervical ganglia, but whether there was here a relation of cause and effect or whether both morbid conditions in the skin and nerves arose from the same cause is a point that necessarily suggests itself. Schwimmer was strongly of opinion that purpura was trophoneurotic in origin. But the facts I have brought forward will not allow of our agreeing with such a dogmatic attitude, especially as physiologists tell us that no certain proof of the existence of specific trophic nerves has been given [39]. In neuralgia, hæmorrhages have been observed at the point of greatest pain, and this repeatedly in successive attacks. Similarly injuries to nerves and nerve involvement in malaria, etc., have led to hæmorrhages. When the innervation of a limb is below par, as in old hemiplegia, a rash may be more marked in it than in the sound one. Thus in a man with an eruption on the legs, the old hemiplegic limb presented many bullous lesions, whereas in the sound one the lesions were papulo-vesicular and not numerous. This was not a purpuric case, it is true, but I mention it as an illustration merely. I have already alluded to subungual hæmorrhages in hemiplegia. This consideration of the nervous system leads me now to refer to the suprarenal glands, and also adrenalin, the hæmostatic properties of which I need not insist on, for according to Balfour, the suprarenals have in the fœtus a twofold origin, the cortex being derived from the mesoblastic tissue, while the medulla is formed by a direct outgrowth from the sympathetic system, consisting at first of an aggregation of neuroblasts. In some animals, *e.g.*, teleostean fishes, the two parts of the gland remain separate throughout life, but in the higher vertebrates the sympathetic outgrowth becomes surrounded by the cortex, and the cells rapidly lose all traces of resemblance to a nerve cell. But the medullary portion is genetically part of the sympathetic system, and its specific secretion, adrenalin, has an action which is apparently confined to that system [40]. The excision of the suprarenal bodies causes a profound fall of blood-pressure; whereas injection of adrenalin increases blood-pressure [41]. It has been suggested, on insufficient grounds it appears to me, that because hæmorrhages into the suprarenal glands were found in some cases of purpura evidently streptococcal in origin, that the suprarenal condition had led to the hæmorrhages in the skin. The explanation appears to me pretty obvious, viz., that both the visceral and cutaneous hæmorrhages depended on the streptococcal infection. Suprarenal hæmorrhages have been found where there was no involvement of the skin in the way of purpuric manifestations. Moreover, in Addison's disease I do not remember ever having seen cutaneous hæmorrhages, nor have I heard or read of such occurring in that disease, nor would one expect anything of the kind on the *à priori* ground that lowering of the blood-pressure is the result of excision of the glands. But in dealing with a subject that requires so much elucidation, it is advisable to keep one's mind open on these points. The changes in the circulation which occur at the menstrual period have been considered to play a part in ecchymotic and purpuric conditions. Danlos [42] and others have published cases of cutaneous hæmorrhages apparently connected with the catemenia. I would here point out that, according to the recent researches of Marshall and Jolly, the changes in the uterus which determine menstruation are due not to ovulation but to an internal secretion from the ovary [43], so that the question arises as to whether the rashes I have referred to, which appear to be connected with menstruation, may not be connected in some way or other with this internal secretion. Howbeit, the extract from another gland, the thyroid, has apparently given rise to rashes with hæmorrhagic tendency. When purpuric rashes occur in pregnancy, the idea of a toxæmia of course suggests itself.

Reviewing what has been stated as to causation and pathogenesis, it is unnecessary for me to call attention once more to the complexity of the problem, so that when one is face to face with a hæmorrhagic rash, treatment must be to a great extent empirical. The first indication, especially where there is any severity of the onslaught, or the condition is complicated by other hæmorrhages, is posture, that is, the horizontal position. Bed alone will do a great deal. As I have already told you it is important to be on one's guard, and the general impression made by the patient must be borne in mind. Cutaneous hæmorrhages may commence in a mild way, but ultimately, perhaps suddenly, more serious symptoms may develop.

The *primæ viæ* are frequently at fault in the erythema purpuricum conditions. Intestinal auto-intoxications must be dealt with by means of saline aperients, etc., but I need scarcely insist, after what I have said, on the need for caution in this direction.

The buccal cavity, especially the teeth, should always receive attention, even when the hæmorrhagic rash does not appear to be directly traceable to the bad condition of the mouth.

In the ordinary run of cases, arsenic and perchloride of iron sometimes answer well. In more severe cases turpentine may prove very useful, but it requires to be administered with caution: ♏x. to ♏xxx. of the oil of turpentine (commencing with the smaller dose and gradually increasing) suspended in mucilage in mixture three times a day immediately after meals, the last dose being taken not later than 6 p.m. Plenty of barley water should be drunk during the treatment. These precautions are necessary to prevent kidney trouble. The urine, it goes without saying, should be examined regularly.

Since Wright's work on the coagulability of the blood and the administration of calcium chloride, this drug has been used, as also lactate of calcium. In some cases I have found calcium chloride of use, but it requires to be pushed before any effect is obtained. When testing a drug, too, with a patient in bed, it is important not to commence its administration at once, but only after some days, to avoid giving credit to the drug really due to the horizonal position of rest. Various other drugs have been extolled, but here the *post hoc, propter hoc* fallacy needs to be warily watched. Perchloride of mercury and gelatine injections have been recommended, but with regard to the latter subsequent experience has shown that complications might arise. In cutaneous hæmorrhages depending on general conditions, such as albuminuria, liver disease, enteric, etc., treatment must be directed to them. The care of such patients may become a difficult matter.

In streptococcal infections antistreptococcic serum would certainly be indicated. And in this connection I would mention rectal injections of polyvalent serum, which answered so well in two cases of severe purpuric rash complicated by other hæmorrhages under Fenwick and Parkinson. In one of these patients the injection synchronised with rapid cessation of the hæmorrhage at a time when death seemed to be only a question of a few hours, so there seems no reason to doubt its efficacy in that case [44].

In a general way, attempts should be made to keep up the patient's strength by the administration of real foods; this is important in bad cases. By real foods I mean raw white of egg, for instance, and not meat extracts. The latter, as foods, whatever they may be as stimulants, always remind me of the man who got a stone when he asked for bread. There is not much to expect from alcoholic stimulants, which are likely to do more harm than good in hæmorrhagic conditions, and are pretty certain to hurry a patient down hill when they arise in the course of infections.

As to adrenalin, its value or otherwise is a point which does not appear to have been decided. But some observers have spoken well of it as well as of ergot. Bandaging the legs carefully may be of use, especially in out-patient cases of hospital practice.

Altogether treatment must depend on the individual case to be dealt with, its merits, surroundings and circumstances. There is no royal road and no specific.

THE

PREVENTION OF TUBERCULOSIS,

WITH SPECIAL REFERENCE TO

TUBERCULOSIS IN IRELAND. (a)

By ROBERT E. MATHESON, LL.D.,

Registrar-General for Ireland.

The question of the prevention and cure of tuberculosis has for some years occupied grave attention in all civilised States in the world.

An International Congress on the subject was held in London in 1901, and a further Congress in Paris in 1905, both of which I attended in my official capacity as a delegate from the Irish Government. The Paris Congress was particularly interesting and helpful, and the French Government spared no pains or expense to make it a really useful conference. It was held in the Palais des Beaux Arts in the Champs Elysées, a magnificent building, eminently suited to the purpose. The Congress was opened by the late President of the French Republic, Monsieur Loubet, and in the opening ceremony delegates from many countries took part. The Museum was a source of practical instruction. On entering was a Bureau of the Prefect of the Seine, where many excellent notices were exhibited warning the public as to the deadly nature of the disease, and the means of preventing infection. Further on was shown a bedroom in an hotel, ill lit and ill ventilated, and side by side with it was presented a model of an hotel bedroom, well lit and well ventilated, arranged by the Touring Club of France. Then a model of a domestic servant's room in a Paris house was contrasted with the model of a cell in the French Prison at Fresnes. Further on there was an ideal sanatorium—a model room in the Lariboisiere Hospital. The Museum contained also many beautiful pathological specimens, and portions of the human body and the bodies of animals affected by the disease in its various forms. There were also many statistical charts, exhibiting the status of the disease in the various countries, and models and designs of sanatoria and of sanitary appliances having special bearing on the subject.

These Congresses have undoubtedly done great service in bringing together those interested in combating the ravages of the disease in the various countries, enabling them to compare notes and discuss together the many practical problems which arise in dealing with the disease.

I cannot, perhaps, open my address this evening in a better way than by showing my audience a copy of the badge issued to delegates and members of the Paris International Congress, 1905. The figure on the badge represents a poor victim of tuberculous disease stretching out her hand and imploring help in her desperate condition. The author of this beautiful design touched a chord of pity in every heart, and lent a pathos to all the deliberations of the Congress. Substituting a fair Irish colleen for her unhappy French sister, we have a picture of what might be represented in many an Irish home, where the flower of youth and beauty are year by year being carried off by this awful scourge.

The august lady, our gracious Vice-Reine, who has organised this Tuberculosis Exhibition, and to whom Ireland is under so deep an obligation for her unceasing activity in promoting every good work tending to the improvement of the country and the amelioration of the condition of its inhabitants, has had the same humanitarian object before her as was before the Paris Congress—viz., how this dreadful disease, which is so fatal in Ireland, can be successfully combated.

In furtherance of this object the first step is, I think, to ascertain clearly how we stand with regard to it, and the information collected and tabulated by my department affords a solid basis on which all administrative action must rest.

Though the registration of deaths only came into operation in 1864, we have statistics of the deaths from pulmonary tuberculosis back as far as 1831. In the Report of the Census Commissioners for 1841 it appears that the number of deaths from consumption, or pulmonary tuberculosis, from June, 1831, to June, 1841, was 135,590. The Commissioners remark that this malady is "by far the most fatal affection to which the inhabitants of this country are subject." According to the Census Commissioners of 1851, the number of deaths from consumption between June, 1841, and March, 1851, was 153,098. The census reports of 1861 record 130,739 deaths from pulmonary tuberculosis between March, 1851, and April, 1861. In the period between April, 1861, and January, 1864, when the registration of deaths commenced, it appears from the report of the Census Commissioners of 1871 that 26,267 deaths occurred from consumption. These figures make the appalling total of 445,694 deaths from pulmonary consumption from June, 1831, to January, 1864, and, having regard to the manner in which the information was obtained, there is no doubt that this total is considerably under the truth.

On January 1st, 1864, the Act for the Registration of Deaths in Ireland came into operation, that for England having been in operation since 1837, and that for Scotland since 1855.

Tuberculosis in England, Scotland, and Ireland, 1864—1906.

In my annual report for 1906 is a chart showing the statistical history of tuberculosis in the three countries from 1864 to 1906. From this it appears that while in 1864 Ireland stood lowest of the three, with a rate of 2.4 per 1,000 living, the rate for England being 3.3, and that for Scotland 3.6, in 1905 Ireland occupied the unhappy position of being the highest with a rate of 2.7, Scotland being next with 2.1, and England lowest with a rate of 1.6. The attention which has been paid to sanitation in the sister countries has doubtless largely conduced to this result, and the chart, an enlarged copy of which is included in my exhibit, loudly calls for a sanitary campaign in this country with a view of reducing our death-rate from this dreadful disease.

But it is not only with respect to the other divisions of the United Kingdom that we are in so disadvantageous a position, but Ireland occupies a lamentably high position as regards death-rate from this malady when compared with other countries. The last annual report of my colleague the Registrar-General for England gives an interesting table showing the death-rates from consumption in various British possessions and foreign states. This table, an enlargement of which is in the Exhibition, deals with pulmonary consumption only, and discloses the sad fact that in the world's records our country stands fourth highest, being only exceeded by Hungary, Austria, and Servia.

Having thus reviewed our position as compared with other States, I now come to consider in detail the status of the disease in this country. In my last annual report I presented a diagram showing the mortality from 22 of the principal causes of death in Ireland in the year 1906. From this diagram (an enlarged copy of which will be found in the Exhibition) it appears that the mortality from tuberculous disease far exceeds that from any other causes of death. Out of a total of 74,427 deaths registered in Ireland in 1906, no fewer than 11,756, or 15.8 per cent., were due to this disease, which is in a great degree preventable. But it is not only that so large a number of our fellow-countrymen and women have been carried off by this scourge but that the mortality is greatest in those ages which ought to form the backbone of our population.

(a) Being a Lecture delivered at the Tuberculosis Exhibition held in Dublin in October, 1907.

My exhibit includes a table showing by sexes and age periods the number of deaths from tuberculosis registered in Ireland in 1906, with the rate per 1,000 living at each age period. This table shows the highest number of victims, and the highest rate per 1,000 living at each age period appear in the period of life from 15 to 45; the age period 15-20 claimed 1,355 victims, or 2.91; the age period 20-25, 1,660, or 3.80; the age group 25-35, 2,821, or 4.37; and that of 35 and under 45, 1,717 persons, or 3.61 per 1,000 living at those ages.

In my annual report for 1905, I gave a diagram showing the proportion of deaths at each age period in England, Scotland, and Ireland in the year 1903. An enlargement of this diagram will be found in my exhibit. A comparison of the ages of the persons who died from tuberculosis in England and Scotland with those who were carried off by that scourge in Ireland, as shown in the diagram, reveals the further fact that the mortality rate from tuberculosis to the number per 1,000 living at those ages in Ireland at the ages 10-15, 15-20, 20-25, 25-35, and 35-45, is enormously higher than it is in England or Scotland.

The explanation of this may, I think, be looked for under two causes:—(1) The emigration from the country for so many years, which has removed the able and healthy, and thus left amongst the residue an increased percentage of the enfeebled and persons less able to withstand the attacks of disease.

(2) The deaths of emigrants who have contracted the disease in other countries, chiefly in America, and have returned to die here. These persons, some of whom were not enumerated in the population, but whose deaths are included in the death-rates shown in the diagram, abnormally swell the death-roll.

(In support of this view Dr. Matheson quoted the reports from several Registrars of Deaths, showing that the death returns were largely increased by returned Irish-Americans, who had been sent back from America by their medical advisers suffering from phthisis. This practice, of course, assists in the spreading of the disease among the poor people at home.)

Though infant mortality in Ireland, as a whole, is much lower than in England and Scotland, the question of tuberculosis amongst infants is an important one, specially in our urban districts. In my annual report for 1906 I presented a diagram showing the infant mortality from 14 principal causes during that year, from which it appears that the infantile victims of tuberculous disease numbered about 400, being equal to a rate of 3.85 per 1,000 births registered. A similar diagram (enlarged) for the year 1905 will be found in my exhibit.

The next point with which I propose to deal is the relative percentage of mortality from the principal forms of tuberculous disease, and their distribution under each sex. This is shown in a diagram contained in my annual report for 1904, an enlargement of which, for the year 1906, is included in the Exhibition. It appears that in 1906 the deaths from phthisis, or pulmonary consumption, were 76.0 per cent. of the total deaths from tuberculosis. The deaths from tuberculous meningitis were 6.8 per cent.; from tuberculous peritonitis and tabes mesenterica 3.9 per cent.; from general tuberculosis 7.3 per cent., and from other forms of the disease 6.0 per cent.

The deaths among males from phthisis were slightly less than those among females, the former being 75.8, and the latter 76.2. The percentage of deaths from tuberculous meningitis was the same for both sexes, viz., 6.8 per cent. The percentage of female deaths from tuberculous peritonitis and tabes mesenterica was in excess of the male percentage, the rate for females being 4.2, and for males 3.7 of the total.

The seasonal mortality from tuberculosis in Ireland is shown in a diagram contained in my annual report for the year 1904. From that diagram it appears that of the total deaths from tuberculosis, 29.1 per cent. were registered in the June quarter, 27.3 per cent. were registered in the March quarter, 22.3 per cent. were registered in September quarter, and 21.3 per cent. in the December quarter of the year.

In my annual report for 1905 is a map showing the death-rate from all forms of tuberculous disease in 1905 for each Poor Law Union (of which there are 159)—the deaths in lunatic asylums and certain institutions being assigned to the Union to which the deceased belonged. An enlarged copy of this map is suspended in the exhibition. From it it appears that in two unions—viz., Lisnaskea, in the County Fermanagh, and Tulla, in the County of Clare—the rate did not exceed 1.0 per 1,000; that in 59 unions the death-rate from tuberculous disease ranged from 1.0 to 2.0 per 1,000 of the respective populations; that in 68 unions the mortality exceeded 2.0 per 1,000, and was under 2.7 per 1,000, which was the average death-rate for all forms of tuberculous disease for Ireland in 1905. That in 11 unions—viz., Antrim, Dingle, Dundalk, Enniscorthy, Larne, Limerick, Listowel, Lurgan, Middleton, Naas, and Rathdrum, the rate exceeded 2.7, but was under 3.0 per 1,000 of the respective populations.

That in 16 of the Poor Law Unions of Ireland—viz., in Banbridge, Bandon, Belfast, Carrick-on-Suir, Castlederg, Clonakilty, Downpatrick, Kinsale, Lisburn, Londonderry, Mallow, Newtownards, Skull, Strabane, Tullamore, and Waterford the rate ranged between 3.0 and 4.0 per 1,000. Finally, that in three Unions the rate exceeded 4.0 per 1,000. In North Dublin Union the highest death-rate from all forms of tuberculous disease was recorded, being 4.76 per 1,000; in Cork Union the rate for the year was 4.53 per 1,000, and in Dublin South Union it was 4.38.

There are not materials for preparing statistics of the mortality from tuberculosis for the whole country by occupations or social positions, but a table will be found in the annual summary of my weekly returns for last year showing the occupations or social position of the persons whose deaths were registered in the Dublin registration area as having died from tuberculous disease during the year 1906. A large table dealing with this subject is included in my exhibit. From this table it appears that of the total deaths, 1,694, representing a rate of 4.5 per 1,000, 6 only belong to the clerical, medical, legal, and other professions, naval and military officers and heads of public departments; that amongst the merchants and manufacturers of the higher class there was only one death; that amongst persons of rank and property (not otherwise described) there were only 4 deaths. In all, amongst the professional and independent classes there were only 11 deaths out of the total of 1,694.

From the middle classes 243 deaths were registered as follows:—11 from the general body of officials, Civil Service, banking, etc.; 49 from traders (excepting petty shopkeepers), business managers, etc.; 120 deaths of clerks and commercial assistants, and 63 deaths of householders in second-class localities, not included in above.

The deaths from tuberculosis among the artisan class and petty shopkeepers numbered 391, and comprise the deaths of 26 working engineers, engravers, printers, watchmakers or jewellers; 115 persons engaged in the building and furnishing trades; 84 in the clothing trades; 127 in other callings ranking with trades, and 20 petty shopkeepers.

In the general service class, of a total of 635 deaths, 27 were employed in the army, police, postal delivery, or prison services; 66 were those of domestic servants; 58 of coach and car-drivers, and vanmen, and 484 were described as hawkers, porters, or labourers. In addition to this, the deaths of 414 persons who were inmates of the workhouses occurred from tuberculous disease. Comparing the mortality in the first four classes, excluding Class V., workhouse inmates, we find that in the professional or independent class the rate was .63, in the middle class it was 2.79, amongst the artisan and petty shopkeepers it was 3.54, and in the general service class it was 4.12. These figures show that amongst the classes which are better housed, clothed, and fed, the mortality from this disease is much less than amongst those who have not the same advantages as regards housing, clothing, and diet, and whose callings expose them more to the severity of the weather than those more affluent in their circumstances.

Causes Favouring the Spread of the Disease.

I now come to consider the causes favouring tuberculosis, and I may mention three principal factors contributing to the spread of the disease:—

1. *Insanitary Houses and Surroundings.*—This is undoubtedly a very prominent cause in disseminating the germs of the malady. The notes on the sanitary condition of their districts, which are supplied to me each quarter by the Registrars, contain many references to this. The Registrar for Cloyne District (Middleton Union) remarks:—"I attribute 40 per cent. of the cases of illness amongst my dispensary patients to overcrowding and the filthy condition of the dwellings, the breathing and re-breathing of vitiated air causing a form of anæmia, accompanied with great debility, lowering the germicidal powers of their tissues, making them easy victims to tuberculous disease." The Registrar for Waterford No. 1 Urban District reports:—"The sanitary conditions in many parts of the district are bad—there are many houses having objectionable surroundings. The housing is in places deficient in air space, light, and ventilation. Tuberculosis is prevalent—it accounts for about 28 per cent. of the deaths." The Registrar for Holywell No. 2 District (Enniskillen Union) states:—"Tuberculosis is on the increase, and, I fear, will continue to be so until more stringent measures are taken to compel the people to pay more attention to the cleanliness of their houses and their surroundings, and particularly to the principle of ventilation and sunlight."

In connection with the influence exercised by insanitary surroundings in promoting tuberculosis, it is interesting to note the low death-rate from tuberculosis which prevails in our Irish prisons, which is doubtless due, in a large measure, to the care exercised by the Prisons Board in regulating the sanitary condition of the cells in which the prisoners are confined, and controlling their dietary. Her Excellency has been presented by Mr. James S. Gibbons, C.B., Chairman of the Prisons Board, with a series of photographs, showing the various descriptions of cells in the Irish prisons, which will be found in the Tuberculosis Exhibition.

2. *Intemperance.*—A further cause which operates more especially in urban districts is intemperance. In addition to the enfeebling of the constitution from over-indulgence in strong drink, the money spent thereon is frequently taken from that required to provide food and clothing for the children, who are thus rendered less able to withstand the attacks of disease.

3. *Neglect of Precautions against Infection.*—A third powerful agent is the practice which largely prevails in this country of living with consumptive patients without any precautions against infection—the result being that one sufferer is liable to infect the whole family. Nothing is more commonly met with than to find a poor consumptive living in a cabin with brothers and sisters, sharing their meals, and frequently sleeping with other members of the family, without the slightest regard to disinfection, and when remonstrated with the answer is, "Sure, it is only a decline." Several other causes might be mentioned, but these will suffice for my purpose this evening.

Remedial Measures.

We now pass to the remedial measures which come within our power to adopt, and these also may be considered under three heads.

1. *The Improvement in the Dwellings of the Working Classes.*—I am glad to say that much has been done in this direction. Those who remember the dreadful cellar dwellings which were to be found in Dublin thirty years ago will feel grateful to our distinguished Medical Officer of Health, Sir Charles Cameron, C.B., for his unceasing exertions to better the housing of the working classes. It is hardly necessary to refer to the deep obligation which the inhabitants of Dublin owe to Viscount Iveagh, K.P., through whose princely munificence large unhealthy areas have been cleared and sanitary dwellings erected. Much, however, still remains to be done, not only in Dublin, but throughout the country generally, if we are to have the terrible tuberculosis death-rate reduced.

2. *Dispensaries, Sanatoria, and Hospitals.*—The second way which is open to us to limit the ravages of the white scourge which paces our land is by the establishment of special dispensaries, sanatoria, and hospitals for the treatment of the disease. As this particular province of the subject will be dealt with by some of my co-lecturers who are professional experts, I need only allude to it here. In addition to the value of sanatoria and special hospitals for the cure of the disease, there can be no doubt that these institutions effect three other great objects:—(1) The alleviation of the symptoms of the poor sufferers, and (2) the withdrawal of the patients, at least temporarily, from their surroundings, in which in all probability they have been infecting others, and (3) the education of the patients and their friends as to the necessary precautions.

3. *Administrative and Educational Measures.*—A third preventive lies in administrative and educational measures. Pulmonary tuberculosis should be made by statute a compulsorily notifiable disease. A resolution to this effect was passed at the special meeting of the Consultative Committee of the Exhibition held on the 12th October. Children at school should be made liable to periodical inspection, so as to have the disease detected in its earlier stages, and hygiene should be taught everywhere in our schools. It is pleasing to note that the Board of National Education have taken this matter in hand, and that in their Programme of Instruction for National Schools, which came into operation on 1st July, 1906, they have directed that simple lessons on health and habits should be given to the scholars.

In bringing this lecture to a close, I desire most earnestly to impress on my hearers the responsibility which rests on the members of the community individually to do their utmost to aid in the efforts which are being made by Her Excellency the Countess of Aberdeen and the Women's National Health Association, as well as by other societies, to awaken the people generally to a sense of their danger. It is my firm belief that if our countrymen and countrywomen were really aroused to the gravity of the situation, their common sense, and intelligence would make them able allies in this great conflict, and that we should soon have to congratulate ourselves on the fact that the excessive mortality from tuberculosis, which is a present disgrace to Ireland, was a thing of the past.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Malignant Disease of the Œsophagus.—Gastrostomy.—Mr. T. P. Legg operated on a man, æt. 61, who had suffered from increasing difficulty in swallowing since the beginning of this year. During the last two or three months he had been able to take nothing but soft solids, and had developed a cough and hoarseness. He had become steadily weaker and emaciated rapidly. A bougie was arrested just below the cricoid, and the smallest size could not be passed through the stricture. There was some thickening in the lower part of the neck, behind, and on each side of the trachea. Laryngoscopic examination showed that the left vocal cord was quite paralysed, and some œdematous swelling over the arytenoid cartilages. With such signs, it was obvious that the part was affected with malignant disease in the upper third of the œsophagus, and it was equally clear that he would succumb to starvation unless something was done to enable him to take more nourishment. In these cases, Mr. Legg pointed out, there are two alternative methods of treatment: either to perform gastrostomy or to pass a tube through the stricture and leave it *in situ*. This latter method was, in his opinion, inferior to gastrostomy. Moreover, it was not always possible to use it. In this patient, a tube could not have been got through the stricture, as the narrowing of the lumen was so great, and the site of the disease being in the upper part of the œsophagus, and close to the opening of the larynx, the part would probably not have retained the tube on account of the cough and irritation set up by its presence. Gastrostomy was, he thought, a very satisfactory operation from the point of view of the patient always being able to take enough nourishment, and it had few drawbacks. As it is performed nowadays, there is very little leaking of the stomach contents, and the skin around the opening rarely becomes excoriated. It frequently is never reddened for more than half an inch, so the discomfort to the patient is exceedingly slight. The operation has a low mortality, if it is done before the patient is extremely exhausted and in the last stages of his illness. The operation is indicated (1) when there is absolute inability to take liquids or solids, provided the general condition is fairly good; (2) when there is great difficulty in swallowing liquid or solids, or there is regurgitation of the nourishment; (3) when coughing is produced every time the attempt is made to take food. One sometimes sees a patient with carcinona of the œsophagus, who is able to take sufficient nourishment without much difficulty, and whose general condition is fairly good. In such a case, gastrostomy is not necessary. One must remember that the operation is a palliative and not a curative one, and therefore is not to be done unless there is a definite indication for it. After the operation the patient always improves for a time; he puts on flesh, is very often able to swallow again by the natural passage, and is benefited in every way. But it is impossible to say how long such improvement will last. Some of the most hopeful cases die suddenly from perforation into the trachea causing septic pneumonia, or from hæmorrhage. Other cases will live a few weeks to three or four months, and occasionally one finds the patient living for twelve or eighteen months. Unfortunately one can never tell beforehand how long the life is likely to be prolonged. But death by starvation can always be avoided, and it should be pointed out to the patient or his friends that this is the chief reason for recommending the operation. In the present case a modification of Franck's method was done. A vertical incision, two inches long, was made through the centre of the left rectus, just below the subcostal angle. A second incision, one and a half inches away from and parallel to the first, was made at the outer border of the muscle, which was split into anterior and posterior layers between the two incisions. A cone-shaped piece of stomach was drawn up into the first incision, and passed between the rectus fibres, so that the apex of the cone appeared at the second incision. Thus the whole cone of the stomach was surrounded by muscle. The apex was stitched to the margins of the second incision, and a hole large enough to admit a No. 10 catheter was made. The catheter was passed into the stomach and fixed by a stitch to the skin, to prevent it dropping in or out of the stomach. The base of the cone was sutured to the rectus muscle and sheath, and the skin incision closed. Before leaving the table four ounces of peptonized milk and 1oz. of brandy were run through the catheter. Mr. Legg said this operation cannot be done if the stomach is much contracted and atrophied; under these conditions one of the other methods has to be selected. The operation just performed gives at least as good results as the others, and is the easiest to perform. There is no danger of septic peritonitis from feeding the patient on the table if the stitching is done accurately. The tube is taken out on the third or fourth day, and subsequently passed when the patient requires feeding.

The patient made a good recovery from the operation; there was no regurgitation through the opening, and he left the hospital much improved in about a fortnight's time. But he died, suddenly, three days later from hæmorrhage.

WESTMINSTER HOSPITAL.

ABDOMINAL TUMOUR — LAPAROTOMY — DISTENDED GALL-BLADDER, GALL-STONES, CHOLECYSTECTOMY.—**MR. TUBBY** performed laparotomy on a female patient, æt. 35 who had the following history: She had suffered some time from pain in the right side below the ribs, and her doctor had detected a swelling. She had been sent up to the Westminster Hospital under Mr. Tubby's care. On admission she proved to be a somewhat spare woman, with a good colour; there were no signs of jaundice. She was able to eat well, and did not at first seem to suffer any inconvenience excepting a dull pain in the right hypochondrium, which was always worse after handling. For three days before operation she had some pyrexia. The diagnosis ot the swelling, Mr. Tubby said, at first was obscure and varying, as its character depended much on the condition of the muscular contraction of the abdominal walls. At times it appeared to extend downwards, and to present characteristics associated with hepatoptosis, more especially as the dulness over the area was variable; but when the muscles were relaxed on subsequent examination, the hands could be made to meet in the right loin, and between them an elongated, hard, tense swelling could be felt running downwards and towards the umbilicus. This swelling was diagnosed as an elongated gall-bladder, probably containing gall-stones. An X-ray examination revealed nothing. Three weeks after admission a laparotomy was performed, and it was at once evident that the diagnosis of gall-stones was correct. As it was probable that the gall-bladder contained pus, a trochar and cannula were introduced, and about three drachms of grumous material were expressed. The gall-bladder was then opened, and three gall-stones removed. One measured half-an-inch in diameter, a second one-and-a-half inches, and a third one-third of an inch in diameter. The large one was tightly grasped by the walls of the gall-bladder, and some force had to be used in squeezing it out. The smallest gall-stone was rounded at that part which looked towards the duct, but was facetted where it came in contact with the large stone. After the removal of the calculi, a probe was passed down to make sure that the common duct was clear. The gall bladder was then removed, the stump being seared with pure carbolic acid, the edges being inverted, and sutures passed so as to bring the peritoneal edges in contact. Strips of gauze were packed around the stump, and the abdominal wound closed, excepting where a small aperture was left for the ends of the gauze strips. Mr. Tubby said that in this case at first there had been considerable difficulty in determining the nature of the tumour, and this illustrated how essential it was that observation of these cases should be prolonged for a correct diagnosis to be arrived at. In such a case, where the symptoms were not urgent, there was no necessity for immediate operation. He thought that sometimes there was undue haste in performing abdominal sections for exploratory purposes, and sufficient time was not given to form a definite opinion of the nature of the case before operation. The operation itself, he remarked, did not differ in any way from the procedure usually practised in these cases, but he considered it was of essential importance to ascertain that the ducts were free from stones, and to carefully examine by palpation the duodenal wall and adjacent ducts, so as to make certain that no calculus was impacted in these situations.

After the operation the patient vomited for three days at intervals, and then began steadily to recover.

TRANSACTIONS OF SOCIETIES.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held on Thursday, October 24th, 1907.

The President, Mr. T. F. Paul, F.R.C.S., in the Chair.

Dr. W. R. **Warrington** gave an account of the clinical features of a patient suffering from

ACUTE HODGKIN'S DISEASE,

who died within two months of the onset of the disease. The spleen was considerably enlarged, the glands only slightly so. There was high fever, diarrhœa, and marked anæmia, and violent delirium preceded death. The microscopic examination of the glands showed the typical structure of lymphadenoma, as described in the writings of Reed, Andrews, and others. Dr. Warrington alluded to the classification of the acute glandular enlargements.

The **President**, Dr. J. H. **Abram**, and Mr. R. W. **Murray** discussed Dr. Warrington's Note.

Mr. R. W. **Murray** related two cases of

EXTROVERTED BLADDER,

in which he had transplanted the ureters into the rectum. In one of the cases he had, ten years previously, performed a plastic operation, whereby an adequate covering for the exposed mucous surface of the bladder had been made, but as the absence of a sphincter to the bladder rendered the patient's life miserable, it was decided to transplant the ureters into the rectum. The patient died on the eighth day after the operation, from ascending ureteral infection. In the second case a similar operation was performed with some success. After operation the patient, a child of 4½ years of age, was able to retain his urine for 4½ hours. For two months all the urine was discharged into the rectum, but recently urine had escaped anteriorly from the right ureteral surface of the bladder. These cases were brought forward to emphasise the high rate of mortality following upon such operations, which he thought probably amounted to 50 per cent.

Mr. R. C. **Dun** agreed with Mr. Murray that the rate of mortality following implantation of the ureters into the rectum or sigmoid flexure was a very high one. In his two cases, one patient died of shock in 24 hours after the operation; the other patient lived two years and then died of diphtheria. The child was only seven years old at the time of his death, but could then hold his water for an hour.

In a third case of extroversion Mr. Dun had performed the first part of Lilienthal's operation, but this had resulted in the patient's death.

Mr. R. C. **Dun** reported a case of

URIC ACID CALCULUS

successfully removed by operation from a child six years old. The symptoms had been indefinite—slight pain in the hypogastrium and hæmaturia. These symptoms were not aggravated by movement. While under observation the hæmaturia was so slight that it could only be detected by microscopic examination of the urine. There was no enlargement of the affected kidney. An X-ray photograph, taken by Mr. Thurstan Holland, very clearly demonstrated a calculus in the right kidney. Mr. Dun drew attention to the rarity of this condition in children, and to the indefinite nature of the symptoms in the case under consideration. He emphasised the importance of radiography as an aid to diagnosis.

Dr. **Macalister** read a paper on

THE PERSONAL FACTOR IN DIET,

in which he commented upon the great variations which exist in the dietetic requirements of individuals. He referred to his experiences among the boys of a large industrial school, and pointed out the fact that collective dieting, although suitable enough for the majority, proved that there is a small minority of people who cannot live healthily on conventional lines. Having spoken on the other hand of the danger of arriving at conclusions as to what is good for all humanity, because a few people thrive on some specialised lines of diet, he pointed to the frequency with which metabolic diseases occur, and that in many cases they result from the introduction of foods which, although suitable for people having perfect metabolic capabilities, are harmful to those in whom they are imperfect. Dr. Macalister directed attention to the complex and mixed character of the human diet, and to the fact that the amount of animal and vegetable food required by different people varies considerably, some needing much meat, others very little, and that there are some who should not take any at all. With reference to these latter, he mentioned a case which had come to his notice two years ago of a gentleman who by instinct and habit was a pure vegetable feeder, and in whom there was a well-marked pair of adventitious mammillæ. He was a strong, athletic man, a particularly fine swimmer, and full of physical and mental energy, and he certainly thrived, and thrives to this day, without taking any flesh of any description. The polythelia, together with the metabolic peculiarity, present in this case, had suggested to Dr. Macalister the possibility of a reversion to some ancestral type of vegetable feeder which might be present in this and kindred cases. He referred to the normal condition of polythelia present in the embryo, and to the possibility that its persistence might be associated with other developmental peculiarities, rendering the persons different in their metabolic powers from those in whom more perfect conditions had been attained to. He thought the appendix was another vestigeal organ, functionless in the wholly developed, but which might be very useful to those perhaps less perfect people in whom it is long and well-developed, sometimes resembling the organ as seen in the herbivorous anthropoid apes, and he suggested that some cases of appendicitis may result from the constant introduction of unsuitable fuel into the furnace of the economy.

Dr. T. R. **Bradshaw** remarked that the theory that special idiosyncrasies in diet might be explained on the ground of development was quite new, and he was not prepared to discuss it. The practical outcome of the paper was to confirm the adage "What was one man's meat was another man's poison." The accepted views on dietary were not satisfactory. The physician who laid down rules for diet was too apt to be guided by his own likes and dislikes. Chittenden's experiments to show that the accepted minimum of food was too high was confirmed by clinical observation. He quoted the case of an elderly lady with pyloric stenosis, who was liable to kinking whenever the stomach was distended. For the past six years she had lived on about a pint of liquid food a day with the addition of a few biscuits, and had maintained her nutrition and was able to take gentle exercise.

Dr. W. **Carter** said that the differences in the constitutional build of men were recognised by the elder physicians who classified them into bilious, phlegmatic, nervous, sanguinary, etc., and treated them both dietetically and medically according to the sub-division in which they ranked them. Dr. Macalister, in his interesting and suggestive paper, had given an indication of what might prove to be a reliable and scientific basis for a more correct classification. He drew attention to the observations of Mr. W. North, communicated to the Royal Society by the late Sir W. Burdon Sanderson. Mr. North said that the gist of the whole matter was that we had to deal with a machine which had a marvellous power of accommodating itself to the work put upon it, which rendered the problem so complicated that the hope of finding any explanation of the phenomena observed was somewhat distant. One man would do an amount of work upon a given diet which to another man would be simply impossible. If the signs given by Dr. Macalister as possibly indicating a partial reversion to an earlier stage of evolution were found, on further investigation, to be reliable, we should have a valuable clue for the dietetic treatment of many cases.

Mr. Harcourt, Dr. W. R. Warrington, Dr. A. G. Gullan, and Dr. Owen T. Williams also spoke.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 27th, 1907.

TREATMENT OF ACUTE RETENTION OF URINE.

WHEN one is called to a patient who cannot urinate, it is easy, says Dr. A. Pappa, in the *Journal des Practiciens*, by a rapid interrogatory and by feeling the vesical tumour, to diagnose a case of acute retention of the urine.

How should the bladder be evacuated is the question. To resolve the problem we have at our disposition different means. Some in current use and which, in the large majority of cases, suffice, others, applicable in case of failure of the preceding and in certain special circumstances.

It is indispensable in the first place to understand the cause of the retention in order to apply a correct treatment.

If the patient is suffering from an affection of the nervous system (hemiplegia, ataxy, paralegia, etc.) the retention should be attributed to this condition, and after having explored the canal with an olivary bougie, a flexible or a coudé catheter will easily be passed. But, in general, the obstacle will be found in the urinary organs themselves, and the diagnosis must be made between prostatitis, spasm, stricture, hypertrophy of the prostate, etc. Examination by the rectum is always necessary to clear up any doubt.

If the prostate is found increased in size, painful, tense and hot, it is a case of prostatitis; if there is fluctuation, an abcess is already formed. If the gland is on the contrary normal, the case is one of spasm or congestion of the urethra.

In all these cases, catheterism should yield the place to medical treatment for fear of carrying infection into the bladder. The better treatment is to order a bath and a very warm enema with a few drops of laudanum. If these means failed then the catheter should be used, but only after the canal had been well irrigated with some antiseptic solution, as oxycyanide of mercury (1—4,000). After which a drachm of a solution of cocain (1 per cent.) is injected to reduce the resistance of the membranous portion of the urethra. Frequently, in case of spasm, by this injection alone, the patient is enabled to micturate and in any case it facilitates the passing of the catheter.

When the patient confesses having had gonorrhœa 3. 4, or 10 years or more previously, or a traumatism of the perineum, and if he complains beside of increasing difficulty in urinating, the diagnosis of stricture imposes itself. The canal should be explored by an olivary catheter of a large size, No. 20; if it does not pass, the size is diminished until the right dimension is found. However, generally, the very smallest calibre fails, and recourse has to be had to one or other of Gouley's whalebone or filiform series. If one of these pass it should be left *in situ*, the urine will pass by the side of it, and the patient will be relieved.

If the patient is close on the sixties, the retention is generally due to hypertrophy of the prostate.

For some time, he has had to get up at night to urinate, the jet was slow in coming; then from some congestion caused by coition, copious repast, cold, voluntary retardation in evacuating the bladder, retention suddenly set in.

Here a catheter coudé is indicated. If resistance is felt, no violence should be permitted, a simple manœuvre is generally sufficient to overcome the obstacle.

The instrument engaged in the posterior urethra and maintained firmly in the median line by the left hand near its extremity and the guide held by the right hand, the catheter is pushed gently towards the bladder, while at the same time the guide is drawn out. By this means the curve of the catheter is accentuated, and the instrument penetrates into the bladder. If the attempt has not been successful a finger might be passed into the rectum to guide the catheter by gentle pressure towards the bladder.

When the catheter has penetrated, should the bladder be completely evacuated? If the patient is young and the retention dates only a few hours, it can be emptied without inconvenience; but if the retention has been more prolonged and especially if the patient is of a certain age, the bladder should not be entirely emptied for fear of hæmorrhage *in vacuo*. After withdrawing a quantity, more or less considerable, according to the case, six ounces of a solution of nitrate of silver (1—1,000) should be injected if the urine is not infected. If, on the contrary, the urine is dirty, it should be replaced at the same time as it is withdrawn by a solution of oxycyanide of mercury. Two or three quarts are thus injected, modifying the vesical contents without having emptied completely the bladder. Complete evacuation should only be permitted after 24 or 48 hours, but the catheterism might be repeated every three or four hours.

Another important question is to know if the catheter should be left *in situ*. In spasm of the urethra or prostatitis, never; in stricture, hardly ever, but frequently in hypertrophy of the prostate, and especially when it is not possible for the surgeon to repeat frequently the operation, and when the patient or his attendants could not be trusted with the catheter.

Where catheritism is absolutely impossible, recourse should be had to puncture of the bladder with Polain's apparatus. The pubis being shaved, a capillary trocar is inserted a quarter of an inch from the edge of the pubis, in the median line, and pushed into a depth of from two to two and a half inches. Aspiration of the urine is made without completely emptying the bladder, and a drachm or two of a solution of nitrate of silver (1—500) injected. The trocar is withdrawn sharply, and the small wound sealed up with collodion.

In general, this operation need not be repeated as congestion disappears from the organs and micturation is re-established, otherwise three or four repetitions may be practised without inconvenience.

There are cases where catheritism should not be practised. In urinary abscess it is dangerous. The abscess should be opened largely, and the patient will urinate through the wound. In grave ruptures of the urethra, catheritism should only be done in the operating room, it being the first operation in external urethrotomy.

In other cases, not only has retention to be treated but also urinary infection, for which a whalebone catheter is insufficient to insure the drainage of the bladder, whereas his indication can be filled by internal urethrotomy permitting the placing *in situ* of a No. 15 or 16 catheter.

Finally, puncture of the bladder is insufficient in case of infection or grave hæmorrhage in prostatic patients. Here suprapubic cystomy should be performed in order to drain largely the bladder by a suprapubic drainage tube or to arrest the hæmorrhage.

GERMANY.

Berlin, Oct. 27th, 1907.

THE TREATMENT OF TETANUS.

PROF. TILMANN, of the Surgical Department of the Academy for Practical Medicine, Cöln, has an article on this subject in the *Deutsche Med. Wochenschrift*, 14.07.

A child, æt. 4, was admitted into hospital suffering from gangrene of the arm caused by a horse treading on it. Immediate amputation was indicated. There was no other injury, but notwithstanding this five days after the injury and two after the amputation, the first symptoms of tetanus made their appearance, the disease proving fatal in another 36 hours. As there was no other injury it must be assumed that the elbow was trodden on, and that the poison was introduced into the system in that way. The early removal of the source of infection had neither cut short the disease nor rendered its character milder. From this it may be assumed that amputation does not promise much in the way of treatment. The case was also of great interest from a pathogenetic point of view. A tetanus poison introduced during the first three days after the injury had not set up any symptoms until five days after. This was difficult to explain. Perhaps the tetanus poison has to develope further in the body before it can do any harm; but in cats the disease shows itself three hours after injection of the tetanus poison.

The case agreed best with the theory of Brunner-Goldscheider, which places the point of difficulty in irritation of the ganglionic cells of the spinal cord. The poison reaches these ganglionic cells by way of the peripheral nerves, or in the nerves themselves to the spinal cord. In this case five days had elapsed before the necessary quantity of toxine had reached the spinal centres, and the toxine formed in the wound during the first three days sufficed to set up the first symptoms of the disease. The interruption of the delay did not help.

Herein perhaps lay the reason why antitoxine did not do much good. Perhaps it was used too late, or not in the right way. Behring recommended that we should protect the threatened spinal centres against the tetanus poison by shutting off the afferent nerves by antitoxine. The writer had carried out this procedure in a case of tetanus following an injury to the knee. The tetanus of a medium type that followed the injury rather quickly was arrested after 52 ccm. of an antitoxine = 280A.E. in the lumbar region and into both ischiatic nerves. Along with this the patient had 0.01 grm. of morphia every two hours and 1 grm. of chloral hydrate. One could not say with certainty that the case would have been fatal without the serum, but in any case recovery took place in a week. Otherwise the author had never seen a case in which he could satisfy himself that the antitoxine was of any value. The cases in which the onset was delayed to about the sixth day almost all proved fatal, those commencing after the tenth day nearly all recovered; in the cases lying between these dates the prognosis was according to the quickness of the onset of the symptoms.

The writer did not make prophylactic injections of antitoxine. When should the injections be made? To make injections into the afferent nerves was not possible. Then it was not free from doubt that injections of antitoxine serum into healthy men did no harm. If tetanus bacilli were found in the wound he injected at once.

AUSTRIA.

Vienna, Oct. 27th, 1907.

Retirement of Professor Politzer.

After 46 years practice in the Allgemeinen Krankenhaus, Politzer has now retired from being the head of the department of Otiatria. A few days since a holiday was recognised by his academic colleagues to present him with a "gold plaquette" and an illuminated address endorsed with the names of subscribers from every part of the globe. Politzer was born on the 1st October, 1835, in Alberti, Hungary, and studied at Vienna under Rokitansky Skoda, Oppolzer, and Carl Ludwig, obtaining the doctorate in 1859.

After a short residence with Ludwig in the physiological laboratory he travelled to Würzburg where Tröltsch was experimenting with the ear; thence he went to Paris where Claude Bernard was electrifying the physiological world with animal experiments in the spinal cord, and finally arrived in London where he took interest in Toynbee's work.

In 1861, when he was only 26 years of age, he returned to Vienna, and was appointed the same year to be a Docent in Otiatria by the general consensus of the Vienna Medical Faculty! His lectures were given in the Medical Klinik of Oppolzer, by the kind permission of the professor. In 1870 he was appointed "Extra-ordinarius" lecturer. In 1873 the faculty began to realise the necessity of a special klinik for ear diseases, and finally resolved that one should be added to the Allgemeinen Krankenhaus with Two Extraordinary Professors, Adam Politzer and J. Gruber; the latter for the male department, the former for the females. In 1896 he was raised to the position of Ordinary Professor of "Ohrenheilkunde," but on the retirement of Gruber next year he was left sole director of the Vienna Klinik for Otiatria.

From 1873 till 1897 his ward consisted of 12 beds, where he operated, lectured, and received guests from every civilised country. He could read and make himself understood in German, Hungarian, French, and English; and before going to the last congress in Madrid added Spanish to the list.

Vienna claims him as the first in Europe to put this branch of medicine on a true scientific basis. Demonstrations of the tympanum and Eustachian tube lead to the practice of catheterising. In his response he told in a humorous way how a notable German "specialist" came to his klinik one day, and after seeing the students go through their exercise, said he had been 40 years in practice and never saw the tympanum before!

His experimental researches and writings are now classic, and found in different languages, a fourth edition of his great work, "Diseases of the Ear and Adjacent Organs" (a) being now before the profession in its English translation. But the greatest marvel of his endurance is the recent completion of the first volume of the "History of Otiatria" in his 72nd year, and means to complete the second volume in his 73rd year of his "Geschichte der Ohrenheilkunde."

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Royal Victoria Hospital, Edinburgh.—The Tuberculosis Problem.—An interesting ceremony took place in connection with this institution on Thursday last, in which the principal part was taken by the Right Hon. A. J. Balfour, who formally opened the newly erected adminstrative buildings. The proceedings took place in a marquee erected in the grounds, and were presided over by Lord Dunedin, who, in introducing Mr. Balfour, said that the hospital, which had been erected as a memorial to the late Queen Victoria, was recognised as a national, not a local, institution, and had been fortunate in receiving the patronage and ready help of their gracious Majesties the King and Queen. After a brief account of the history of the hospital from its commencement as a dispensary for tuberculosis, by Dr. R. W. Philip, and remarks by Dr. Underhill, President of the Royal College of Physicians, as representing the medical profession, and by Dr. Leslie Mackenzie, representing the Local Government Board, who dwelt on three aspects of the crusade against consumption—viz., compulsory notification, hospital isolation for advanced cases, and curative sanatorium treatment for the early stages—all three of these existing in Edinburgh—and who also alluded to the recent Act amending the Public Health Act so as to make the latter applicable, without undue hardship to patients, to all forms of infectious disease, Mr. Balfour addressed the audience on the tuberculous problem, and in his speech showed that he had a thorough and statesmanlike grasp of the problems at issue. He paid a graceful tribute to Dr. Philip as the inventor of the idea of a tuberculosis dispensary ten years before it was adopted in any other locality or country, which is rightly to be looked on as the central point in the general campaign against tuberculosis. Most of those present could remember a time when tuberculosis was not regarded as an infectious disease, but since Koch's great discovery we had learned that phthisis, like many other diseases, was due to an invasion of the body by organisms, just as plague, scarlet fever, and small-pox were. Different though all the infectious diseases were, methods of treatment were of three types. We might take, for example, the method of dealing with them by some form of inoculation, long known in the case of small-pox, lately introduced with so much effect into the treatment of other diseases. Then we had the method of diminishing the danger of infection—one of the great objects of the medical reformer being by isolation, by early treatment, and the like, to save those who are not infected from such a strength of invasion as will overcome their natural endowment in the way of resistance with which no one was wholly unfurnished. Yet, said Mr. Balfour, I do not anticipate that we shall ever banish the tubercle bacillus completely from any great tract of country inhabited by man. But though this be so, we can, I suppose, reduce its power of doing evil to an incalculable degree. We have before us what has been done with regard to typhus; it may be that our children will live to see the time when consumption shall be as little known in our midst as typhus is to-day. We have arrived at a condition of affairs in regard to that particular disease so satisfactory that the force of resistance of the community at large is adequate to prevent its making any kind of lodgment in our midst. That is the ideal to which we look forward with regard to tuberculosis. The third method of dealing with this infectious disease is by taking those who are attacked and restoring to them their powers of resistance so that they can throw off the disease and return to their ordinary work re-endowed with powers rendering them immune to any similar invasion. This is the object of sanatoria, and we shall never be able to deal adequately with this subject unless we get into the popular mind the distinction between the various methods of dealing with the disease, and not attempt to do in sanatoria what can only be done in hospitals, or to do in the hospital what can only be done in the sanatorium. The fundamental truth must never be lost sight of—consumption is a disease which can be dealt with if you take it early, but if you allow it to get a fatal grip on the organism, all you can do is to smooth the dying months of the sufferer, but in no sense can you restore him to his place in society or his work in the world. After the address, which was frequently applauded, the Rev. Dr. Macgregor moved a vote of thanks to Mr. Balfour, and Sir Alexander Kinloch paid a similar compliment to the chairman. Sir Alexander Christison presented to Mr. Balfour a silver key with which to open the new buildings. This concluded the formal proceedings, and thereafter the institution was thrown open to the inspection of those present.

(a) Published by Bailliere, Tindall and Cox, and revised by the author.

Notification of Births Act.—The Local Government Board have issued a circular in reference to the adoption by local authorities of this Act. After detailing the provisions of the measure, the Board observe that, in their opinion, there is no need to impose the obligation of notifying births unless steps are taken to carry out the ultimate object of the measure—viz., the giving of advice and instruction to those having charge of the infants. In ordinary circumstances they would not be prepared to consent to the adoption of the Act, unless it appeared that arrangements had been made for this purpose. Local authorities proposing to apply for consent for the adoption of the Act ought, therefore, to be in a position to show that such arrangements have been or would be made.

Royal Crichton Asylum, Dumfries.—Dr. C. C. Easterbrook has been appointed Superintendent of this Asylum, in succession to Dr. Rutherford, whose resignation was announced some weeks ago. Dr. Easterbrook is at present Superintendent of Ayr District Asylum, previously to which he was senior assistant at Morningside.

BELFAST.

Cerebro-Spinal Meningitis.—The epidemic of cerebro-spinal meningitis dies out by slow degrees, two or three cases being notified each week still. There are only five cases of the disease under treatment at the Purdysburn Fever Hospital, as most cases are now treated at home. It appears that a considerable number of cases were secretly kept at home even during the height of the epidemic, when the authorities removed all cases which were reported to them to the fever hospital. Cases of deafness are turning up at the special hospitals, some of which were never recognised as cerebro-spinal meningitis, or, if they were recognised, were never reported.

The Prevention of Consumption.—An important conference took place on Thursday last, when delegates representing the various sanitary authorities in the north-west of Ireland met in Londonderry to discuss measures for the prevention of the spread of tuberculosis. Sir John B. Johnston, chairman of the Londonderry Committee on Tuberculosis, presided, and in addition to the leading men of the district Professor McWeeney of Dublin was present. His Excellency the Earl of Aberdeen telegraphed his good wishes, and Lady Aberdeen wrote promising to attend a meeting at a later date to found a local branch of the Women's National Health Association. After a statement by Professor McWeeney on the subject of tuberculosis, various resolutions were passed, including one advising the adoption of a scheme for providing a sanatorium. The Mayor entertained the delegates to luncheon, and in the evening a lecture was delivered in the Guildhall by the Registrar-General, Dr. Matheosn, B.L., on "Tuberculosis in Ireland." He stated that of the deaths registered in Ireland last year no fewer than 11,756, or 15.8 per cent., were due to tuberculosis, which was in a great degree preventable.

LETTERS TO THE EDITOR.

QUACK MEDICINES.—THE DISCLOSURE OF TRADE SECRETS.

To the Editor of The Medical Press and Circular.

Sir,—If any further evidence be needed to prove the necessity for an authoritative inquiry by a Royal Commission or by any other equivalent means, into the trade in "proprietary articles," it may be found in the report under the above heading in *The Times* of Monday, October 23rd. On Tuesday last Captain R. Muirhead Collins, the representative of the Australian Commonwealth in London, received a deputation (introduced by Mr. K. B. Murray, of the London Chamber of Commerce) of some twenty manufacturers of proprietary medicines, to protest against the proposal that their wares should in future be made to bear labels stating their composition. To assist the Australian Government in eradicating harmful nostrums the deputation expressed their willingness to make a declaration that their articles do not contain any of the drugs which may be prohibited, or any deleterious drugs in quantities injurious to health. The deputation was evidently composed entirely of manufacturers engaged in the preparation of useful articles, such as recognised varieties of foods for invalids and infants, disclosure of the composition of which would evidently destroy legitimate trade secrets. A declaration such as they proposed to supply would undoubtedly meet their case, but such a declaration would have no value, even if true, when emanating from the deliberately fraudulent concocters of quack nostrums and panaceas. It seems a pity that the deputation did not recognise this difficulty and suggest means to dissociate themselves from a traffic which must be as repugnant to them as to all honest men who are acquainted with the facts. The majority of quack medicines are virtually inert; few of them, whatever their pretensions, contain anything more potent than a small cheap purgative dose; whilst many of them, including cures for epilepsy, for organic kidney and liver diseases, and for all surgical diseases, including cancer, are nothing more than coloured and flavoured water, perhaps with a few added grains of some common drug; or, when in the form of ointments, made up of cheap lard coloured and disguised, but lacking any drug of recognisable potency. It is easy for the proprietors of such compounds to declare that they contain nothing harmful. The harm they do is by inducing simple people, misled by cunningly-worded lying advertisements, to rely upon them when their disease is due to organic pathological activity. Functional dyspepsia may sometimes not be made much worse by delay whilst reliance is placed upon some "liver" or "indigestion" cure; but delay in a case of gastric ulcer (a very common occurrence among the poor and ignorant) may lead to a disastrous termination. A bogus heal-all ointment, disguised fat, is harmless in itself, but cases often occur when a wretched patient with some surgical disease, perhaps cancer, which in an early stage was amenable to operation, has allowed the malady to pass into a hopeless phase whilst trusting in the promises of cruel and cynical knavery. These examples, as no medical reader needs reminding, could be extended to vast lengths. Suffice it to say that disclosure of the constituents of advertised quack medicines, and of the structure of bogus apparatus, such as sham electric belts and mechanical cures for deformity, or for deafness, would demonstrate at once, not only to skilled witnesses, but to cultured men of the world, that the trade is merely a cloak for plunder, and ought to be mercilessly suppressed. The trade in "baby quieters" which seems to be enormous in Australia, and which was specially denounced by Mr. Beale, would not be stopped by a declaration such as the deputation suggested. Many of these mixtures are virtually inert frauds; the harm is done by reliance upon them instead of attention to the cause of the infant's disquiet—nearly always improper food and feeding. When baby soothing medicines contain narcotics and anodynes, which perhaps cannot be classed as "drugs injurious to health," they help by masking the pain to lead the infant towards death, or to survival as a ricketty and "scrofulous" wastrel. They form, as Mr. Beale pointed out, a potent contributory factor in the prevailing preventible infantile mortality, and the direct cause of death in large numbers of instances.

I am, Sir, yours truly,

Henry Sewill.

OBITUARY.

THOMAS MICHAEL DOLAN, M.D.Dubl., F.R.C.S., L.R.C.P.Ed., L.S.A., OF HALIFAX.

We regret to record the death of Mr. Thomas Michael Dolan, of Halifax, which took place on the 22nd inst., after an illness of many months, at the age of sixty-three. Deceased was a native of Cashel, county Tipperary. His medical training was at Durham and Steeven's Hospital, Dublin. In 1869 he was appointed medical officer of the Union Workhouse, a position he retained to the time of his death, and in that office assisted in the carrying out of several reforms, notably the erection of special hospital wards and the substitution of professional nurses for pauper attendants. He was the author of several works on medical subjects. One of these, published in 1878, was his "Rabies and Hydrophobia." In the hydrophobia competition for a prize offered by Mr. V. F. Bennet Stanford, in 1879, and open to all nationalities, Dr. Dolan sent in a contribution so full of merit that, on the recommendation of the adjudicators, the special prize of £50 was raised and awarded to him. He wrote a good deal on life insurance, and in 1881 he secured a prize of £100 in a competition on this subject instituted by the Equitable Life Assurance Company of the United States. The following year he obtained the Roylston Prize, amounting to 300dols., for an essay on "Sewer Gas: Its Physiological and Pathological Effects on Animals and Plants." and in the next year he won the prize given by the Medical Institute of Valencia, Spain, for his essay on "Heart Disease." In recognition of these successes his brother practitioners in Yorkshire entertained him to a complimentary dinner. Dr. Dolan wrote much in various medical journals on the question of workhouse infirmaries and their medical service. In 1885 he undertook the editorship of the "Provincial Medical Journal," and continued as such until he established the "Scalpel," a medical periodical which attained a high place. He became F.R.C.S. of Edinburgh in 1879, and a Doctor Medicine of the University of Dublin in 1883.

WILLIAM HENRY DAY, M.D.St.And., M.R.C.P.Lond.

We regret to announce the death of Dr. William Henry Day, M.D., late of Manchester Square, who died on October 22nd, at Meopham, Kent, at the age of seventy-six. After studying at Bristol and King's College, London, he was admitted a member of the Royal College of Surgeons (England) in 1854, took the M.D. degree of St. Andrews in 1857, and ten years later became a member of the Royal College of Physicians (England). In the Crimean war he was assistant-surgeon to "The Buffs." He was a member of several learned societies, had been secretary to the Harveian Society, and was consulting physician to the Samaritan Hospital for Women and Children. Dr. Day was a considerable contributor to medical literature, his manual on "Diseases of Children" running through two editions.

DEPUTY-SURGEON-GENERAL ROWLAND WIMBURN CARTER, M.D.Calcutta, M.R.C.S., L.S.A.

We regret to record that Deputy-Surg.-Gen. R. W. Carter, of the Army Medical Staff, retired, died on October 20th, at Southsea, in his 77th year. He was admitted a member of the Royal College of Surgeons, England, and a licentiate of the Society of Apothecaries in 1854, and joined the Army Medical Service the same year, serving with the 20th Regt. throughout the Crimean Campaign of 1854-5, including the Battle of the Alma, the siege and fall of Sebastopol, and the capture of Kinbourn. He also took part in the Indian Mutiny Campaign of 1858, and was thanked by the Viceroy and his Royal Highness the Commander-in-Chief for his ability during the cholera outbreak in India in 1859. He served in the Afghan War in 1878-80, receiving another medal, and retired in 1884 with the honorary rank of deputy-surgeon-general.

SPECIAL ARTICLE.

A DESTRUCTOR OF DISUSED TINS IN THE TROPICS.

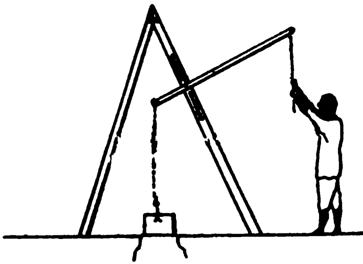
THOMAS MICHAEL DOLAN, M.D.Dubl., F.R.C.S.,

Acting Medical Officer of Health, Freetown, Gold Coast.

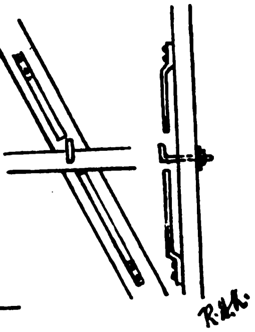
To anyone acquainted with the prominent position occupied by old empty tin vessels in tropical sanitation, suggestions regarding improvement in the method of their disposal will not appear unreasonable. The subject, however, is so closely connected with hospital sanitation that there need be no hesitation in introducing it to the attention of medical readers. The number of empty tins which have contained sardines, potted meats, vegetables, cigarettes, oil, etc., etc., and which will be found in the neighbourhood of houses in the Tropics is almost incredible unless one has witnessed it. Many of these tins when first discarded are appropriated by small dealers and the native poor, who in turn throw them away after some time as useless.

In Freetown, Sanitary Inspectors' systematic visits from house to house, street to street, result in most of these tins being deposited in dust-bins, from whence they are removed by the Sanitary Authority to "dumping grounds" as half-way houses, or to "shoots" for direct deposit in the sea. In other towns remote from the sea the tins are usually buried in pits. The chief sanitary objection in the Tropics to empty tins being allowed to remain as rubbish, is due to their capability of containing water and so favour mosquito breeding. If, then, every tin was crushed as soon as it was empty of its original contents, its water-retaining capacity would be almost entirely obliterated, and it would occupy less space in transport and disposal, the latter being obviously especially important if the disposal has to be by burial. Inasmuch as this crushing on the premises of the individual users would be extremely difficult to arrange for, the next best thing seems to me to provide means for crushing the tins at a "dumping ground." They could be "weeded out" and so dealt with, while the consumable (packing) material is burnt.

I propose a very simple form of crusher which could be easily made in most urban localities, even in the Tropics. It consists in a lever working on a tripod stand; to the end of the short arm is attached a weight which is raised by depression of the long arm and allowed to fall on the tin placed on a nether stone set in the ground. I have not seen this suggestion made for dealing with waste tins in the Tropics,



CRUSHER.



FULCRUM.

though it appears to me such an obvious proceeding that I can scarcely believe it can be novel. I do not suggest that bottles should be dealt with in the same way.

LITERARY NOTES.

MESSRS. CASSELL AND CO. announce a new illustrated serial, "Everybody's Doctor," to be completed in twenty-four parts at 7d. It promises to deal with every kind of common ailment, and to provide common sense information, and, where possible, plain remedies. Medical men will have to look to their laurels!

⁂

DR. SEYMOUR TAYLOR has issued a reprint of his lectures on "Acute Pneumonia." The first deals with the ætiology, symptomatology, prognosis, and complications of pneumonia, and also refers somewhat fully to the pathology of the disease. The second lecture is devoted to the consideration of its treatment. These lectures are interesting reading and give a systematic account of the whole subject.

⁂

THE last monthly number of the *Canadian Journal of Medicine and Surgery* is published in connection with the meeting at Montreal of the Canadian Medical Association. This number is specially worthy of notice as not only containing several excellent original communications, but also on account of the forty pages of half tone illustrations showing views of hospitals, public buildings, and places of natural beauty in various parts of the country.

⁂

WE have recently received a work, entitled "The Wife: Her Book." It is written by Mr. Hadyn Brown, L.R.C.P.,Edin., and published at 3s. 6d. net by Messrs. Sisley's (Ltd.). There is much that is good and wholesome in the book, but its value is marred by the introduction of unnecessary details on "delicate subjects," and of nerve-harassing tales of servant girls who gave birth to illegitimate children. Surely such stories are not suitable reading for young expectant mothers, or even for any woman, who may be expected to buy a book of this nature.

⁂

MESSRS. ROBERT BOYLE AND SON have issued a booklet in which they plead for a natural system of ventilation. The plea we imagine will not fall on deaf ears. As we have often pointed out fresh air is fresh because it is fresh, and not because it is strained and filtered and sprayed and pumped. The complaint usually made by those who live in rooms artificially ventilated is that they feel heavy and stupid after a few hours in the atmosphere provided; which is not surprising when it is considered that all freshness has been taken out of the air. The problem of ventilation is to provide houses with fresh air without draughts, and not an atmosphere, of whatever degree of purity, which has as little sparkle as boiled water.

⁂

FROM the Calendar of the Royal College of Surgeons of England just published we learn that there are 1,387 Fellows on the roll of the College, of whom 1,341 obtained this distinction by examination, 27 were elected as members of 20 years' standing, 17 Fellows by election, and one Fellow elected *ad eundem*. There are 17,544 Members, 398 Licentiates in Midwifery, and 2,111 Licentiates in Dental Surgery. The D.P.H. granted by the Royal Colleges of Physicians and Surgeons is held by 601. The income from all sources during the year amounted to £24,326 17s. 8d., the largest item being derived from fees paid by candidates for the diplomas of the College, £15,219. The expenses for the year amounted to £22,648, leaving a balance at the bankers of £288 10s. 10d. From the Librarian's report it appears that the supply of books has been well kept up during the past collegiate year. Early in 1907 a new library with an annexe was fitted up in proximity to the gallery of the large library, affording additional accommodation.

⁂

"ROYAL Leamington Spa: Its Springs, Baths, and General Attractions." By John Murray Moore, M.D., M.R.C.S., F.R.G.S.. (Leamington Spa: Burgis and Colbourne, Ltd., 1907.) The latest of the many *brochures* written in praise of "leafy Leamington" is a well-intentioned, enthusiastic, and somewhat egotistical but withal interesting and informing description of the ways and waters and other delights of this justly-favoured of our English inland health resorts.

⁂

THE late Sir William Gairdner was the author of a charming work on "The Physician as Naturalist," but it has been chiefly left to the surgeons to found museums which have served as permanent means for the scientific study of Nature. Mr. Jonathan Hutchinson is not only a surgeon of world-wide distinction, but he is an enthusiastic clinician of the field as well as of the ward, and has exemplified in many ways his far-seeing wisdom by providing for the needs of the teacher and the requirements of the student in the establishment of museums both in town and country. Such a volume as that now before us (*The Haslemere Museum Gazette*, edited by Jonathan Hutchinson, F.R.C.S., F.R.S., assisted by E. W. Swanton, Vol. I., Bale and Sons) gives a glimpse into an encyclopædial mind, and provides a storehouse of facts, a record of observations, a fascinating realm of treasures, all of which have lessons or suggestions. It is impossible to indicate the varied and multitudinous items of interest in this volume. Here are astronomical and geological notes, anthropometric data, zoological descriptions, sketches of marine botany, conchological illustrations, pathological details, and much concerning man and his doings. Such a wonderful collection of scientific fragments is rarely brought within book covers. Mr. Hutchinson in this book gives fresh evidence of his virility and versatility.

MEDICAL NEWS IN BRIEF.

Charge of Attempted Abortion.

JOSEPH TOCKERT, 32, was indicted at the Central Criminal Court, on October 22nd, for conspiring, with Agnes Jane Taylor and another person unknown to use on Taylor an instrument with intent to procure abortion. Sir Charles Mathews, in his opening statement, said that Agnes Jane Taylor resided with her husband at Beckenham. In the summer of 1906 Mr. and Mrs. Taylor, who were then residing in another neighbourhood, made the acquaintance of the prisoner. In October of that year Mrs. Taylor made a communication to her husband, and subsequently left their house without his knowledge. Subsequently Mr. Taylor met the prisoner, and Mr. Taylor then informed him of the communication which his wife had made to him, which was to the effect that there had been intimacy between them. About Easter in the present year Mrs. Taylor made another communication to her husband, in consequence of which Mr. Taylor wrote to the prisoner. At an interview, Mr. Taylor told the prisoner that his wife had gone to Lowestoft with him under the impression that he was going to provide a home for her. The prisoner replied that it was true that they had done so. On hearing that, Mrs. Taylor, who had been in the room during the interview, went out, and returning a few minutes afterwards, told them that they were talking to a dead woman, as she had poisoned herself. Mr. Taylor gave her an emetic, sent for a doctor, and she recovered. She had taken five grains of morphia. Early in September Mrs. Taylor became ill, and died. A *post mortem* examination disclosed the presence of wounds, showing that an illegal operation had been performed, which had set up blood poisoning. The prisoner was arrested, and said he knew nothing whatever about it. At the conclusion of the evidence for the prosecution counsel for the defence submitted that there was no case to go to the jury. There was no evidence of any conspiracy. Mr. Justice A. T. Lawrence said he did not think that there was a case that it would be safe to leave to the jury. The facts were quite consistent with the defence that the woman got the operation performed without the prisoner's knowledge and against his wish. He directed the jury to return a verdict of not guilty. The jury found the prisoner not guilty. Mr. White said the prisoner had been committed for trial at the Maidstone Assizes upon the coroner's inquisition for the murder of Mrs. Taylor.

Society for the Relief of Widows and Orphans of Medical Men.

At a quarterly Court of the above Society held recently, Dr. Blandford, President, in the chair, one new member was elected and the death of one was reported. It was decided that a Christmas present of £544 be divided among the annuitants of the Charity, each widow to receive £10, each orphan £3 and the orphans on the Copeland Fund £5 each. Since the last court a donation of £100 had been received from the executors of the late W. Catlin, Esq. Mr. Catlin was elected a member of the Society in 1860. Five letters had been received from widows of medical men who had not been members of the Society asking for relief, but for this reason in each instance it had to be refused, as relief is only granted to widows or orphans of deceased members. Membership is open to any registered medical practitioner, who at the time of his election is resident within a 20-mile radius of Charing Cross. Full particulars and application forms may be obtained from the Secretary, at the offices of the Society, 11, Chandos Street, Cavendish Square, W. The Secretary attends there on Wednesdays and Fridays from 4 to 5 should a personal application be desired.

St. Vincent's Hospital, Dublin.

The annual dinner of St. Vincent's Hospital was held in the Shelbourne Hotel on the 22nd inst. Dr. McHugh presided. After dinner, the toasts included "The King," and "St. Vincent's Hospital," proposed by the President; "Our Past Students," proposed by Dr. Cox, and replied to by Mr. Tobin; "Our Guests," proposed by Mr. McArdle, and replied to by his Honour the Recorder of Dublin, Dr. Magee Finny, and Dr. McWeeney. The dinner was well attended and excellently served.

PASS LISTS.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on 22nd inst., with the following results:—

First Examination, five years' course.—Of 31 candidates entered the following seven passed the examination:—James Macrae, Caithness; Harold L. de Forges Garland, Oamaru, N.Z.; Haripado Chatterjee, Calcutta; Ruttonbai Nazir, Bombay; Kathleen Reed, Calcutta; Thomas Hardie, Glasgow; and John R. Fleming, Airdrie; and five passed in physics, and one in chemistry.

Second Examination, four years' course.—Of two candidates entered one passed the examination, viz., Adeline M. Watts, Travancore.

Second Examination, five years' course.—Of twenty-seven candidates entered the following nine passed the examination:—Bickford J. Hattam, Melbourne (with distinction); William M. Thomson, Lisburn; Herbert C. Bankole-Bright, West Africa; Henry E. K. Fretz, St. Kitts; Conrad J. Arthur, Grenada; Ulick J. Bourke, London; Charles K. Carroll, India; John W. Robertson, Edinburgh; and William G. Forde, Co. Cork; and three passed in physiology.

Third Examination, five years' course.—Of twenty-nine candidates entered the following sixteen passed the examination:—William T. Lawrence, New York; Millicent V. Webb, Warwick; William G. Forde, Co. Cork; Michael Mulrain, Trinidad; Sakharam Bhagwat, India; William Grant, Arbroath; Shivnarain Rozdon, Simla; Ian MacLeod, Scotland; Dakshina R. Das Gupta, Calcutta; Hugh S. W. Roberts, Wales; Charles W. Kay, Lucknow; John J. Huston, Ireland; Martin Remers, Manchester; Helen Y. Campbell, Natal; Clement H. Heppenstall, Lincoln; and Framroz M. Vajifdar, Aden; and one passed in pathology, and two in materia medica.

Final Examination.—Of eighty-six candidates entered the following thirty-three passed the examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—Shanker P. Gogte, India; Oscar A. McNichol, Canada; Cecil Berry, Wigan; Surendra K. Sen, India; Lionel W. Bradshaw, Wakefield; Helen Y. Campbell, Natal; Horace J. Williams, U.S.A.; Charles A. Ritchie, Nova Scotia; Alban L. B. Best, Melbourne; Frederick B. Elwood, Belfast; Leo Murphy, Midleton; Charles Nyhan, Dromgarriffe; Samuel T. White, Canada; William P. Dillon, Canada; Osler M. Groves, Canada; Arthur Saldanha, India; Percival T. Rutherford, England; Roderick McLennan, Australia; Graham Smith, Ashbourne; Bandla R. Naidu, India; Carunguli S. Mudali, Madras; Crichton R. Merrillees, Australia; George S. Williamson, Scotland; David D. McNeill, Orkney; Ronald Wingrave Duncan, Edinburgh; Claribel F. van Dort, Ceylon; James S. R. Weir, Ireland; Shivshankar R. Soneji, Bombay; Walter Damms, Sheffield; Henry F. Collins, Madras; John A. H. Muller, India; Vinayak S. Sanzgiri, Bombay; and John Miller, Scotland; and eight passed in medicine and therapeutics, two in surgery and surgical anatomy, ten in midwifery, and ten in medical jurisprudence.

The following candidates having passed the requisite examinations of the Conjoint Board in October were admitted Diplomates in Public Health:—William H. E. Brand, Banchory; Douglas Bell, Barrow-in-Furness; John Hunter, Cockburnspath; Hubert J. Norman, Winkleigh; Alexander C. B. McMurtrie, Edinburgh; John Ritchie, Edinburgh; William A. Wilson-Smith, Duns; Alice M. Burn, Edinburgh; Agnes J. Gardner, Edinburgh; Rose Hudson, Edinburgh; Ethel Wiseman, Edinburgh; John McKenzie, Leith; Sohrab M. Hodiwalla, Edinburgh; and Thomas R. Smith, Edinburgh.

At the same Sederunt the following gentlemen passed the first examination in public health:—David J. Roberts, Carnarvon; John N. Meade, Caithness; James S. Edwards, Edinburgh; Mark S. Fraser, Edinburgh; Alfred B. Darling, Edinburgh; and William J. MacKinnon, Biggar.

Trinity College, Dublin.

During Michaelmas Term, 1907, the following candidates passed the Intermediate Medical (Part I.) Examination:—David L. M'Cullough, Euphon M. Maxwell, Charles W. M'Kenny, Richard H. Mathews, Henry H. James, Walter E. Adam, John Gardiner, Hans Fleming, William M. Johnstone, Samuel R. Richardson, Francis J. A. Keane, Victor W. T. M'Gusty, Robert V. Dixon, and Gervase W. Scroope.

Previous Dental Examination.—Physics and Chemistry, Arthur A. Smith; Anatomy and Institutes of Medicine, James I. Kelly; Materia Medica, James I. Kelly and Ernest S. Friel.

Apothecaries' Society of London.

The following candidates, having passed the necessary examinations, have been granted the L.S.A. Diploma, entitling them to practise medicine, surgery, and midwifery:—H. J. W. Barles, A. G. Gamble, C. G. Grey, and E. Wharton.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Liver Cirrhosis in Children, following Scarlatina.—Latterly considerable importance has been attached, especially by the French physicians, to the ætiological rôle played by the infectious diseases in the production of cirrhosis of the liver in children. Bingel (*Jahrb. für Kinderheilk.*, h 65, S 393), now refers to several fatal cases of scarlatina in children, in whom the liver was investigated, and in all of which there was found more or less well marked small round celled infiltration of the periportal tissue. Here and there also there were found patches of necrosis and of cloudy swelling of the liver cells. The further fate of these necrotic areas has been found to consist in a gradual replacement by connective tissue, and the consequent establishment of a genuine cirrhosis. Slight evidence of regeneration of cells was also obtained in the presence of very large multinucleated liver cells at the periphery of the necrosed patches, while a large increase in the number of the smaller bile ducts was also noted. M.

Deposition of Fat and Fatty Acids in the Intestinal and Mesenteric Lymphatic Tissues.—Whipple (*Johns Hopkins' Hosp. Bulletin*, September, 1907, p. 382) writes of "A Hitherto Undescribed Disease" characterised anatomically by the lesions indicated above. The patient was a man, æt. 36, who had been perfectly healthy up to five years previously, when, on going abroad, he began to suffer from pains in the joints, which were very persistent, and from chronic cough. This condition lasted for about four years, and then a chronic diarrhœa became established, with some swelling of the abdomen. The motions were found to contain enormous numbers of fatty acid crystals, and to be white and creamy in appearance. The blood was practically normal, as was the urine, till shortly before death, when some acetone was detected. There were no tubercle bacilli in the sputum, and no re-action followed the injection of tuberculin. A laparotomy was performed, and the mesenteric glands were found to be greatly enlarged, but no attempt could be made to deal with them. Shortly afterwards death occurred with all the symptoms of acetonæmia. At the autopsy the mesenteric glands were found to be greatly enlarged and somewhat elastic to the touch, of an opaque pale yellowish colour, and containing in little cyst-like pockets small yellowish granules. Microscopically these granules were composed of fat globules and numbers of long acicular fatty acid crystals. Numerous giant cells were seen, and a general increase of the connective tissue stroma. The villi of the small intestine were enlarged, the epithelial lining being normal, and the submucous tissue being swollen and packed with deposits of fat and fatty acids similar to what were found in the glands. A peculiar cell with abundant foamy protoplasm and a pale vesicular nucleus was found in both glands and intestinal mucosa. Numerous other changes were found in the remaining viscera, but nothing specially characteristic; some sections of the glands stained by the Levaditi method demonstrated the presence of a peculiar rod-shaped organism which did not stain by the aniline dyes. The writer discussing the case concludes that the symptoms were due to some obscure disturbance of fat metabolism, but of what exact nature it is as yet impossible to say. He suggests the name Intestinal Lipodystrophy as the one at present most applicable to the condition. M.

The Pathology of Acute Lymphocythæmia.—Dudgeon and others give an account (*Journal of Path. and Bact.*, January, 1907) of the pathological changes found in three cases of acute lymphocythæmia occurring in young adult males. The most striking feature in each case was the leucocytic infiltration of the various viscera, the vast proportion of the cells met with being large and small lymphocytes. Mitosis in the lymphocytes was observed, but not to any marked extent; and coarsely granular eosinophil cells were almost entirely absent. This change was even noticeable in the bone-marrow, in which over 95 per cent. of the cells present were of the non-granular type. No free iron was found in any of the viscera. The red cells of the blood were much diminished in number, and in one case a large number of nucleated red cells were found. The white cells were increased, and the total number steadily increased as the disease progressed. Some fine fatty change was present in the viscera of one case. Microscopically numerous capillary hæmorrhages were found scattered throughout the body: the spleen was enlarged in every case, and in one instance contained several infarcts; the lymphatic glands were universally enlarged and in one case somewhat softened; the thymus gland was greatly enlarged in two cases. M.

The Fœtal Circulation Through the Heart.—Pohlmann reviews the more important theories dealing with this subject (*Johns Hopkins' Hosp. Bulletin*, October, 1907, p. 409). These he points out are three in number, viz.—(1) Sabatiers' theory that the currents of blood in the right auricle cross one another, that of the inferior vena cava being directed to the foramen ovale, and that of the superior vena cava entering the right ventricle. This he characterises as physically impossible, morphologically inaccurate and developmentally unnecessary. (2) Wolff's theory that the blood of the superior vena cava entered the right ventricle, and that that of the inferior vena cava was evenly distributed between the two ventricles. (3) Harvey's theory that the blood from the two venæ cavæ became mixed in the right auricle, and that the mixture was then distributed to both ventricles. This theory the writer believes to be the most correct, and to accord best with the results of his own investigations. He obtained experimentally answers to the following queries:—(1) Do both ventricles expect the same amount of blood? This was answered in the affirmative. (2) In what proportion does the inferior vena cava return blood to each ventricle? The answer to this was that it returned it in equal amounts to both ventricles. This result favoured both Wolff's and Harvey's view, but the answer to the third question (3) in what proportion does the superior vena cava return blood to both ventricles? decided finally in favour of Harvey's view, by showing that blood from that vessel was found evenly distributed in the outflow from the two ventricles. M.

The Wood-Tick and Spotted Fever.—Our knowledge of the relation of insects to the spread of disease is constantly growing, and Ricketts (*Journal of the American Medical Association*, October 12, 1907) adds to that knowledge by the report of his experiments on the relation of the wood-tick of the Rocky Mountains to the spotted fever of Montana. He comes to the following conclusions:—(1) Infected ticks exist in the known infected districts. (2) Both the adult male and the adult female may acquire the disease by feeding on an infected animal, and may transmit it to a normal susceptible animal for a period of several weeks thereafter. (3) During either of its intermediate active stages, larval or nymphal, the tick may acquire the disease in the same manner, retain it during moulting, and prove infective when it reaches the subsequent active stage. (4) The infected female may transfer the disease to the young through the egg.

(5) The virus exists in both the salivary glands and the intestine of infected ticks at a certain time; as it also invades the female generative organs, the condition is probably one of generalised infection. The disease is not highly destructive to the tick. Ricketts concludes by urging the destruction of the tick in the infected districts by the same means as have been found effective in dealing with the cattle-tick of the Southern States. R.

The Pathology of Chorion-Epithelioma.—Schmauch (*Surgery, Gynæcology, and Obstetrics*, September, 1907) enters a protest against the current view of the pathology of chorion-epithelioma. He regards this condition not as a true neoplasm, but as what he terms a "cellular infection." By this he appears to mean an invasion of the maternal tissues by certain of the cells or tissues of the placenta-villi or syncytium or both. In some cases this invasion is very slight in degree, and does not transgress the uterine mucosa, whereas in others it may infiltrate the uterine wall, or even give rise to emboli and metastases in the lung. The question whether the epithelial cells thus transplanted or misplaced will be able in any given case to proliferate or not depends on the reaction between them and the tissues into which they stray. It is impossible by microscopic examination of one nodule of the growth to decide whether it is a harmless embolus or part of a generalised metastasis. "There is only a gradual difference," says the author, "between the simple invasion of the uterine muscles by villi and their sequelæ, such as adherent placenta, the common and destructive placentary polyp, and the common and destructive mole; between the localised chorion-epithelial growths, limited to the uterus and placental region, and the villous infarcts, developed by deportation of villi; and finally between those cases in which the lungs were able to retain and master the scattered fetal cells (mostly syncytial and atypical forms), and the typical chorioepithelioma malignum, which becomes generalised through general metastases. Only the latter two types deserve the name of malignant chorioepithelioma." The practical conclusion the author comes to is that the malignancy of so-called chorion-epithelioma is to be judged, not by microscopic examination of part of the growth, but by the general clinical symptoms. This view is upheld by analysis of a large number of cases. We are not able to distinguish, we confess, between what he terms "cellular infection" and neoplasm, in the absence of knowledge of the fundamental pathology of neoplasms. A neoplasm may very well be, in the widest sense, a cellular infection. This point, however, does not tell against the view that there are all degrees of chorion-epithelioma from the perfectly innocent to the definitely malignant. R.

Tumours of the Bladder.—Mandlebaum (*Surgery, Gynæcology, and Obstetrics*, September, 1907) furnishes a valuable paper on the pathology of tumours of the bladder. He divides tumours of the bladder into three groups:—(1) An epithelial tissue group, including papilloma, carcinoma, adenoma, and cysts. (2) A connective tissue group, including fibroma, myxoma, and sarcoma. (3) A muscle-tissue group, the myomata. Primary bladder tumours comprise about 0.7 per cent. of all tumours, and of bladder tumours 90 per cent. occur in males. Of the epithelial tumours 65 to 75 per cent. are malignant. McKenna gives a careful description of the histology of the various forms, which does not differ, however, from the usual description. He notes that papilloma of the bladder not uncommonly passes into carcinoma. The distinction can only be made with certainty by the aid of the microscope, though a papillary tumour which is tightly bound to the bladder wall may with certainty be pronounced carcinoma. Microscopically, the transition shows itself by a proliferation of the epithelium into the stroma, while at the same time it loses its typical arrangement. When squamous celled carcinoma occurs in the bladder, it is due, says the author, to a metaplastic formation of squamous epithelium, the result of chronic inflammation. He has examined five cases of scirrhus of the bladder, four of which, however, were secondary to tumours of the prostate. In two cases of adeno-carcinoma the disease was also secondary to disease of the prostate. The author holds, however, with Limbeck that glands may and do occur in the bladder, and that primary adeno-carcinoma of the bladder has been found. Cysts of the bladder are uncommon, and are said to originate from glands or to be the result of congenital defects connected with the urethra, the Wolffian body, or Gärtner's duct. Myxoma occurs mostly in childhood, and in structure resembles the ordinary nasal polypus. An interesting case of endothelioma infiltrating the base of a papilloma is described. R.

Anomaly of the Cœliac Axis.—McKenna reports (*Surgery, Gynæcology, and Obstetrics*, September, 1907) an anomaly of the cœliac axis of some importance to surgery. The usual division of the vessel into gastric, splenic, and hepatic arteries maintains, but the hepatic artery runs directly into the gastro-duodenal, giving only a rudimentary branch to the liver. The gastric artery, normally the smallest of the three, is large and gives off the large branches which supply the liver. The surgical importance of the condition lies in the fact that in resecting a part of the stomach, some operators are in the habit of doing a preliminary ligation of the gastric artery. If the latter should be supplying the liver, the results would be disastrous, since the arteries of the liver are terminal. It would, therefore, be well for surgeons, before tying the gastric artery, to examine the hepatic vessel. R.

Diphtheroid Organisms in General Paralysis.—Candler (*British Medical Journal*, September 28, 1907), from the result of his own experiments, criticises the findings of Ford Robertson as to the presence of diphtheroid organisms in the blood, fluids, and tissues of general paralytics. He examined the blood, cerebro-spinal fluid, respiratory, alimentary, and genito-urinary traces of the cadaver; the urine and urethras, and the blood and cerebro-spinal fluid during life. The total number of cases examined was 223, 82 of which were cases of general paralysis, and 131 of other forms of insanity. The incidence of diphtheroid organisms in general paralysis was 12.2 per cent., while in other forms of insanity it was 8.4. The highest individual percentage of organisms occurred in the urethras of general paralytics, viz., 16 per cent., compared with 13.6 per cent. in other forms of insanity. The number of cases being small, the statistics cannot be regarded as giving trustworthy results. The examination of the blood and cerebro-spinal fluid was, however, entirely negative. In no single instance was a diphtheroid bacillus observed either in smear or in culture from the blood or cerebro-spinal fluid. The examination of *post-mortem* material Candler regards as very unsatisfactory, owing to the rapidity with which all sorts of organism invade the tissues after death. Moreover, the presence of diphtheroid organisms on the mucous surfaces of perfectly healthy people is by no means rare, and the greater frequency with which it has been found in general paralytics is insufficient to justify any conclusion as to causal relation. R.

Primary Cancer of Vagina with Auto-Inoculation.—Wilson (*British Medical Journal*, September 28, 1907) records a case of the rare disease—epithelioma of the vagina, with the rarer phenomenon of auto-inoculation or contact infection. The disease was present in the shape of two ulcerating patches, one on each side of the entry of the vagina. By the microscope they were found to be exactly similar in structure, conforming to the most common type of cancer of the vagina—the squamous celled. The spread from one side to the other is best explained as auto-inoculation or contact infection or implantation. Similar metatasis from one labium to the other has been recorded more than once, and implantation in the vagina of adeno-carcinoma of the uterus has also been recorded. R.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

M.R.C.S.—Atropine was first recommended by Trousseau in the treatment of asthma. In some cases it acts most beneficially, and has even effected permanent relief. But there is no certainty as to its results.

Enquirer.—Your letter shall receive an early answer.

Pensator.—We cannot express an opinion upon the case without knowing more of the facts. If our correspondent will communicate further with us we will endeavour to advise him. The position, we gather, is an involved one. but whether the ethical point raised can be maintained or not is apparently doubtful.

CURE-I-CAN COMPANY.

The following note from the *Financial News* is not without a certain interest and significance of its own. Company registered by Jordan and Sons, Limited, 120, Chancery Lane, W.C. £20,000 (£1). To acquire the business of preparing and selling "Cure-I-Can" ointment carried on by R. K. Hull, F. W. Dawson, E. Bush, and P. Macdonald, at Leicester, as the Macdonald "Cure-I-Can" Company. No initial public issue. First directors (not less than three nor more than seven): R. K. Hull, F. W. Dawson, E. Bush, and P. Macdonald. Qualification (except P. Macdonald, who requires none), £1,000. As fixed by company.

Student.—The alcohol question, just like vivisection and vaccination and other debatable subjects, will never be settled by argument. Statistics improperly used can always be made to prove anything.

Mr. R. Stewart.—We shall be pleased to give space to a reply to our correspondent.

Dr. Adolf Erdos.—We have made inquiries, and find a company which will. We are communicating with you privately, enclosing prospectus.

EXPECTATION OF LIFE.

A writer in the *Journal of Health* of Paris seeks to plan out the course of life as follows:—First year—infantile complaints and vaccination; second year—teething, croup, infantile cholera, and convulsions; third year—diphtheria, whooping-cough, and bronchitis; fourth year—scarlatina and meningitis; fifth year—measles. By now half the children are dead. The others live on as follows: Seventh year—mumps; tenth year—typhoid; sixteenth year—chlorosis and spinal irritation; eighteenth year—neurasthenia; twentieth year—cephalalgia, alcoholism, and vertigo; twenty-fifth year—marriage (considered, presumably, as a disease). In the twenty-sixth year—insomnia; thirtieth year—dyspepsia and nervous asthenia; thirty-fifth year—pneumonia; forty-fifth year—lumbago and failing sight; fifty-fifth year—rheumatism and baldness; sixtieth year—amnesia, loss of teeth, hardening of arteries; sixty-fifth year—apoplexy; seventieth year—amblyopia, deafness, general debility, loss of tone in the digestive ogans, gouty rheumatism. For the seventy-fifth year is given death—*i.e.*, if there is any body left alive.

Jamaica.—It is rather beyond our ken to say whether there are any hospitals in British Colonies solely officered by coloured doctors and nurses without reference to any European, but we imagine this may be the case in some of the more unhealthy Colonies. It may, however, be a point to refer to the emergency hospital which was exhibited last May at Jamestown (Virginia) at the celebration of the tercentenary of the landing of Captain John Smith. This hospital had negro doctors and nurses entirely, and was provided with the most up-to-date fittings of every description.

Meetings of the Societies, Lectures, &c.

Wednesday, October 30th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. H. L. Barnard: Clinique. (Surgical.) 5.15 p.m.: Lecture: Mr. T. Collins: Myopia.

North-East London Post-Graduate College.—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Thursday, October 31st.

Harveian Society of London (Stafford Rooms, Titchborne Street, Edgware Road, W).—Papers:—Dr. B. H. Spilsbury: Lymphatism in Relation to Death under Anæsthetics. Dr. S. Phillips and Mr. G. French: Cases of Lymphatism.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. E. W. Brewerton: Sympathetic Ophthalmia.

North-East London Post-Graduate College.—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson), X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappell). 4.30 p.m.:—Lecture: Mr. H. W. Carson: Surgical Disorders of Digestion.

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Seborrhœa and Psoriasis dealt with as Stages of the same Dermatitis in Symptoms, Diagnosis, and Treatment.

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. Corner: The Irreducible Inguinal Herniæ of Female Children.

Friday, November 1st

West London Medico-Chirurgical Society (West London Hospital, Hammersmith Road, W.).—8.30 p.m.: Clinical Meeting. Cases will be shown at 8 p.m.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. C. A. Parker: Clinique. (Throat).

North-East London Post-Graduate College.—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Great Northern Central Hospital (Holloway Road, N.).—3 p.m.: Clinical Lecture:—Dr. Horder: Some Points in Connexion with Oral Sepsis (illustrated).

Central London Throat and Ear Hospital (Gray's Inn Road, W.C.).—3.45 p.m.: Demonstration:—Mr. Stuart-Low: Middle Ear and Labyrinth.

Appointments

Dingle, Percival A., L.R.C.P.Lond., M.R.C.S.. Medical Radiographer to the North-Eastern Hospital, Hackney Road.

Hatherell, Robert Ratcliffe, M.R.C.S., L.S.A., Medical Officer and Public Vaccinator for the Topsham District by the St. Thomas's (Exeter) Board of Guardians, and also Certifying Surgeon under the Factory and Workshop Act for the Topsham District of the county of Devon.

McCollum, J., M.B., Pathologist to the City of London Hospital for Diseases of the Chest.

Pratt, J. H., M.R.C.S., L.R.C.P.Lond., House Physician to the City of London Hospital for Diseases of the Chest.

Vacancies.

King Edward VII. Sanatorium, Midhurst, Sussex.—Pathologist. Salary, £250 per annum, with board, lodging, and attendance. Applications to the Hon. Secretary, 19 Devonshire Street, Portland Place, W.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £150 per annum, with apartments (not board). Applications to the Honorary Secretary, Mr. G. A. Lightfoot, 23, Castle Street, Carlisle.

Leicestershire and Rutland Asylum.—Junior Medical Officer. Salary, £130 per annum, with board, lodging, and washing. Applications to W. J. Freer, Esq., 10 New Street, Leicester.

Down County Infirmary.—House Surgeon. Salary, £60 per annum, with board, etc. Immediate application to Dr. Tate, Infirmary House, Downpatrick. (See Advt.)

House of Recovery and Fever Hospital, Cork.—Junior Assistant Resident Medical Officer. Salary, £50 per annum, and board. Applications to John Marshall Day, Medical Superintendent. (See Advt.)

Royal National Hospital for Consumption for Ireland.—Resident Medical Officer. Salary, £300 per annum, with house. Applications to Hon. Sec., 13 South Frederick Street, Dublin. (See Advt.)

Births.

Gould.—On Oct. 24th, at Castle Hill House, Shaftesbury, the wife of Harold Utterton Gould, M.B., B.C., of a son.

Greene.—On Oct. 21st, at 124 Crossbrook Street, Cheshunt, the wife of William A. Greene, M.R.C.S., of a son.

Haines.—On Oct. 23rd, at Winfrith, Dorset, the wife of Frederick H. Haines, M.R.C.S., L.R.C.P., D.P.H., of a daughter.

Horder.—On Oct. 19th, at 141 Harley Street, London, the wife of Thomas J. Horder, M.D., F.R.C.P., of a daughter.

Marriages.

Dawson—Platt.—On Oct. 22nd, at St. Anselm's. Davies Street, London, George W. Dawson, F.R.C.S.I., of Portman Street, to Amy Melliar, widow of Frederick Platt, of Barnby Manor, Newark, and eldest daughter of the late Rev. P. G. Ward, vicar of Braughing, Herts.

Gwynn—Downward.—On Oct. 22nd, at the parish church, Whitchurch, Salop, Charles Henry Gwynn, M.D.. to Caroline Mary Downward, only daughter of the late John Downward, Esq.

Moss—Parker.—On Oct 24th, at St. Thomas' Cathedral. Bombay, Edward L. Moss, R.A.M.C., only son of the late Edward L. Moss, F.R.C.S.I., staff-surgeon R.N., to Eileen Emily, younger daughter of Colonel Parker, R.E., retired.

Deaths.

Day.—On Oct. 22nd, at Meopham, Kent, William Henry Day, M.D., late of 10 Manchester Square, London, aged 76.

Hodgson.—On Oct. 21st, at Malvern Wells, in his 90th year, William Pritchit Hodgson, M.R.C.S.E., L.S.A., late 73rd Regt.

Lightfoot.—On Oct. 23rd, at Trevor House, Leyburn, John Parker Lightfoot, M.R.C.S., L.R.C.P., aged 39.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, NOV. 6, 1907. No. 19

NOTES AND COMMENTS.

Materialism v. Medicine.

IN an interview with "General" Booth, some few months ago, the great Salvationist was asked whom he considered the most dificult people to convert. We feel a little ashamed to say that he did not show much hesitation in replying "Doctors; and nurses next." Apparently, therefore, medical men are not only obdurate to the "General's" arguments, but they infect their subordinates with their disbelief. It is, of course, impossible either to prove or to rebut such an indictment, but it is a great pity that good people do not leave medical men to enjoy that liberty of conscience which is one of the greatest blessings of the realm. A religious contemporary deplores the fact that "medical science appears more than ever inclined to find a physical basis for moral qualities"—a statement which seems to show that the organ in question has less grasp of the relativity of mind and matter than even medical scientists themselves. And that, alas, is little enough. But perhaps if there is one prominent factor in the situation, it is the almost complete extinction of the old materialism, which is as rare as the old unbridled individualism of the type that opposed the Factory Acts on the ground of their interference with the liberty of trade. Exact scientific knowledge of the body may keep medical men from falling into the extravagant idealism of Christian Science, but it equally does not land them in the morasses of *Kraft und Stoff*.

Medical Thrift.

It is not often that one has the pleasure of recording practical evidence of the growing popularity of orthodox medicine in the community, but there was an announcement in the papers last week which shows appreciation in a quarter in which it was little expected. "Burglars," it ran, "have broken into South African Institute of Medicine, at Johannesburg, and stolen a quantity of medicine." We do not remember ever having seen crime take this particular form before, but we may congratulate ourselves that in these days of "therapeutic nihilists," when even the most cherished beliefs of our forefathers are called in question, the virtues of drugs still exercise a strong hold on the imagination of the Bill Sykes of South Africa. We would that more detailed information had been furnished, as it would have been interesting in the extreme to learn how the robbers disposed of their plunder. Did they devote themselves to an orgy of calomel and castor oil? Or did they merely select a few items of arsenic and prussic acid for their inconvenient friends? We must await the verdict of history on these questions, but, in the meantime, we are inclined to fancy that the pursuit of pharmacological experiment must have thrown its spell over them, as it does over the eager youths who are induced to enter at the medical schools in the month of October.

Flower Cure.

IT will be impossible in the future for any medical man to sing, without severe scientific reservations,

"The flowers that bloom in the spring, tra-la,
Have nothing to do with the case."

It appears, indeed, likely that they will have a great deal to do with the case, that is, if it be one of insanity. The discovery of the therapeutic value of flowers have been made at the very appropriately named "Bloomingdale" Institute for the Insane, White Plains, U.S.A. Rows of lovely sweet-smelling flowers are placed in rich profusion before the inmates of that asylum, and it is found that the weaker their minds the stronger the influence of the flowers upon them. A few sniffs and a gaze or two have an astonishing effect; paroxysms are calmed, violence evaporates, and philosophical discourse replaces the incoherent mutterings of mania. Statistics as to cures and as to their permanency are not yet obtainable; perhaps the flower treatment has not been sufficiently long on trial; but probably by the time they are forthcoming the Americans will have discovered something even more efficacious, and the figures will be no longer needed. At least the craze—we should say treatment—is harmless, so long, that is, as the flower-pots are not used as weapons of offence, and as evidence of humanity to the insane we are glad to hear of it. What we should like even more to hear is that some steps of a very drastic nature had been taken to make impossible the shocking barbarities lately reported, with regard to the way the insane are treated in the reputedly civilised State of Illinois.

And a Fruit Cure.

THE transition from a flower asylum to a fruit hospital is not an abrupt one. It is announced that a bazaar is shortly to be opened in aid of the "Fruitarian Hospital" in Kent. We confess to an almost reprehensible degree of ignorance as to what a fruitarian hospital is. We know of hospitals for animals, for domestic pets, and even for boots and shoes, but we have never yet come across one for sick apples and sleepy pears. There may, for aught we know, be a "felt want" for such a "new innovation," but the institution in question apparently is not to supply it, for mention is specifically made of funds being wanted to build a children's ward. Are the children then to be fed entirely on fruit—and, if so, on what fruit? Our own knowledge of pediatrics suggests several conditions in which it would be difficult to advise a purely fruit diet, and others in which it would prove distinctly disadvantageous to be cut off from such animal products as milk or such vegetable ones as bread. However, we see that Lord Llangattock is honorary treasurer of the hospital, and we know that his lordship has sympathies already wide enough to include anti-vivisection propaganda and pheasant battues. Perhaps from the products of the latter he is able to supply nitrogenous nutriment when needed.

Inquisitorial Methods at Manchester.

If there is one principal more than another necessary for health authorities to recognise, it is that they rule as representatives of the people, and that the efficacy of their administration depends entirely on how far they carry the people with them. Medical men who pass much of their time in the bedrooms of the poor are far more in touch with the sentiments of the working class than political organisers and party journalists, and we may add, usually far more in sympathy with their just complaints. It appears from what passed at the reception by the Sanitary Committee of the Manchester Corporation of a deputation from the Manchester Medical Guild, that officials of the health department of that city have been acting in a high-handed, offensive, and inquisitorial fashion to patients supposed to be suffering from various infectious diseases who prefer to remain in their own houses, and under the care of their own medical men. Sanitary inspectors, it seems, frequently have the impertinence to enter the bedrooms of sick people, to cross-question them, and even to override the diagnosis of the patient's own doctor. Such proceedings, let us say at once, are insufferable, and none the less so because done in the name of hygiene. To call them un-English is the mildest term that can be applied; to call them outrages on the privacy, decency, and self-respect to which the meanest are entitled would not be at all too strong. We are delighted to see the medical men of Manchester protesting against methods which, apart from everything else, can only bring into loathing and disrepute everything connected with sanitation.

LEADING ARTICLE.

FIRES IN HOSPITALS.

Last week an alarm of fire arose in the largest of our London hospitals. Fortunately, the outbreak, which took place in a laundry on the ground-floor, was promptly extinguished by fire hydrants brought into operation by members of the staff and by the timely arrival of the Fire Brigade. Had the conflagration involved the rest of the hospital the consequences must have been terrible indeed. The wards are large, old, and are more or less continuous from one end to the other of a most extensive and irregular pile of buildings. This incident obviously suggests the desirability of guarding against such disasters by the abundant provision of fire extinguishing appliances, and by the periodical drilling of the whole of the staff in their use. The real lesson, however, to our mind lies far deeper, and we venture to draw the attention of the Metropolitan Hospital Funds to the necessity of the proper construction of all buildings used for the housing of sick persons. Of recent years great strides have been made in the scientific construction of fire-resisting buildings. Wood has been to a great extent replaced by iron, and, given iron girders, it requires little additional outlay to supply floors of incombustible material. The simple addition of stone staircases to such floors constitutes a virtually if not an actually fireproof building. At any rate, the safety of the helpless patients within the walls of a hospital would be enormously enhanced by the adoption of precautions that are suggested by considerations of ordinary prudence and humanity. Of what use is it to provide succour and shelter for the sick poor if we pack them into combustible buildings where they may at any moment be burnt alive. It is no answer to say that such occurrences are rare. Several disasters of the kind have occurred in the United Kingdom, notably one within the past few years, but others of considerable magnitude have happened in other parts of the world. It may be asking too much that all old hospital buildings be demolished and replaced by properly-constructed fire-resisting structures. On the other hand, we can, and do, demand that henceforth no additional hospital premises be erected unless they comply with modern requirements as regards safety from fire. We trust that in future the King Edward VII., the Hospital Sunday, and the Saturday Funds will adopt this condition as one of the chief planks of their policy. Further, as medical charities are universal, it is to be trusted that a similar attitude will be assumed by governing bodies in every part of the United Kingdom. Apart from voluntary supervision, there is another aspect of the question. Why should not local authorities assert their right to control the structural stability (as regards fire risks) of hospital premises? Theatres and other places of public amusement are most carefully and rigorously controlled in this respect. If theatres, why not hospitals, which are permanently inhabited by a manifestly helpless population? If the law of the land be insufficient, so far as the powers of local governing bodies are concerned, then let it be strengthened so as to confer upon those responsible for the protection of the community this elementary capacity for increasing the safety of hospital buildings. It is for the public to insist that henceforth all hospitals shall be built of fire-resisting materials and be properly constructed on fire-resisting lines.

CURRENT TOPICS.

A Costly Asylums Report.

The eleventh annual report of the Asylums Committee of the London County Asylums has just been issued. It is a bulky volume 224 pages large folio size. It includes a great number of reports and an immense mass of statistical information, some of it doubtless of value for future reference, but we venture to assert that a large percentage of the detailed information is absolutely useless to the outside world. If we turn to p. 41, for instance, we find among the accounts sent in from individual asylums an item of 3s. 9d. for "providing and fixing a small shelf in the surgery." The mere printing and publication of this item must cost the ratepayers a considerable proportion of 3s. 9d.. A more absurd and indefensible extravagance it would be hard to imagine, for after the bills are passed by committees and accountants there is surely no need to print details. A little wise pruning would cut down the substance of the book considerably without detracting from its scientific value, or from its efficiency as a control over expenditure. Then, again, we cannot imagine that any practical purpose is served by the printing of many charts (some coloured) and tables on interleaved sheets. The cost of this volume must have been great: we imagine it cannot have been less than £1,000 or £1,500, if we include the work of editing and distribution. As a curious commentary on the diffuse elaboration of this production we may say that we have looked in vain among the mass of accounts for a statement of the cost of production of the annual report. The only presumable entry bearing on the point is that of expenditure on "stationery, printing, postage," etc., to the various asylums amounting to a total of £4,775 7s. 10½d. The ratepayers have themselves to thank if they permit this extravagance to continue without protest. The London County Council, although a non-elective body, has a number of strong and powerful delegates from the various metropolitan boroughs. For many years past The Medical Press and Circular has pointed out the extravagance of the Metropolitan Asylums Board, although at the same time it has been freely admitted that the public, on the whole, has been fairly well served in the matter of infectious disease accommodation, and extremely well so far as ambulance is concerned. In our opinion it is desirable that the constitution and methods of the Board should undergo a Governmental inquiry.

Mr. Birrell and the Tuberculosis Problem.

The deputation from the General Council of Irish County Councils which waited on the Chief Secretary for Ireland last week in reference to the tuberculosis problem in Ireland, received a certain amount of reward for their trouble. They can hardly, indeed, have expected that the full extent of their demands—the provision of sanatoria by the Government—would be granted, since the Treasury is notoriously shy of taking new responsibilities. Mr. Birrell, however, promised that he would strongly urge on the Treasury to contribute to the cost of sanatoria if erected by the local authorities. We are glad to note that the Chief Secretary distinguished carefully between two classes of sufferers from tuberculosis for whom relief is necessary—those in the incipient stages and those who are incurable. Much confusion has arisen from carelessness in not noting that the nature of the relief required is very different for these classes. Mr. Birrell made the useful suggestion that the derelict workhouses throughout the country might be used as sites for the requisite hospitals and sanatoria. He also promised his support to the proposal to make tuberculosis a compulsorily notifiable disease, though we do not quite see his objection to attaching the usual penalties to breach of the law in this respect. In conclusion Mr. Birrell approved of the suggestion that the Local Government Board should be authorised to send lecturers throughout the country, who should educate the people in the means of preventing tuberculosis. The various measures will, if carried into effect, start the campaign against tuberculosis in good earnest.

A Bishop upon Toothache.

The relation of the teeth to the general health is now becoming recognised generally by the "man in the street." A most striking object-lesson was given to that interesting person in the wholesale rejection of recruits during the South African war on the score of defective teeth. It is well that he should have settled convictions upon so important a subject, inasmuch as the destinies of the nation must in the long run be guided by his intelligence. As a sane and reasonable person, he will at once endorse a recent utterance of the Dean of Manchester to the effect that everybody should visit the dentist twice yearly. The justification for that general rule is to be found in the omnipotent maxim which declares prevention to be better than cure. Bishop Welldon, when headmaster of Harrow, used sometimes to say that if any boy complained of toothache, he would give him a hundred lines, on the ground that either he or his parents had not taken the trouble to guard against a perfectly preventible pain. This homespun wisdom is clearly capable of wide extension. Were it applicable to public health an enormous preventive field would at once be thrown open, inasmuch as the major part of disease, according to scientific views, is preventible. Unfortunately, the relations of health authorities to their populations are not quite on all fours with those of headmasters and scholars.

Certificates in Tropical Medicine.

The Royal Colleges of Surgeons and Phycisians of England have decided to grant certificates in tropical medicine to students of the London School of Tropical Medicine who have passed certain special examinations. The certificates are endorsed by two assessors appointed by the colleges, who restrict the privilege to their own diplomates. The wisdom of this new departure appears to be somewhat questionable. The new diploma—for that is virtually the result—simply adds to the chaos of existing qualification; nor is it altogether obvious why the diploma of full medical qualification should not include a knowledge of tropical diseases. The nearest analogous special distinguishing title is that of D.P.H., but the specialism of public health and that of tropical medicine are poles asunder. Then, again, the fact that the London colleges restrict the certificate to their own diplomates embodies the spirit of exclusiveness and of the close corporation that is hardly worthy of the present days of liberal enlightenment. It is tolerably certain that the powerful School of Tropical Medicine which was the first to appear on the medical horizon, will not permit its students for any length of time to remain at any disadvantage that may be attached to the absence of a certificate of proficiency in their special subject.

Boric Acid in Sausages.

Last week a London grocer was fined £5 and costs for selling sausages containing twenty-six grains of boric acid to the pound. Apart from the fact that boric acid may be in itself injurious, there is the obvious objection that by its use the maker may be able to palm off tainted meat upon his customers. In any case, the deliberate finding both of the legal Bench and of the scientific sanitarian is against the use of boric acid as a preservative, a verdict which has the tacit approval of the medical profession. Under such circumstances it is somewhat surprising that a prosecution of the kind under consideration should be of sufficient rarity to attract special attention. There must be an enormous number of sausages adulterated with a similar preservative in other districts of London, where the health of their inhabitants should be no less a matter of solicitude than it is in Wandsworth. As a matter of fact, the infrequency of prosecutions for adulteration of food and drugs suggests a lack of proper public supervision in that particular direction. There are many ways in which local authorities might be brought to book. It would be within the power of any ratepayers' protection society, for instance, to collect and analyse a certain number of samples of various articles bought at random, and to regulate their action according to results thus obtained. Without any great stretch of imagination, it may be surmised that data of considerable practical interest might in many instances accrue from such a step.

Professor Koch and the Crocodiles.

SOME recent reports of the work of Professor Koch in East Africa bids fair, if confirmed, to lead to results of a far-reaching nature. He has found that the *glossina palpalis* breeds not only on the banks of lakes, but also along the streams in the interior right up to their source. He has also observed that the fly in question feeds mainly upon the blood of crocodiles, whereby the deadly trypanosome is spread among those reptiles, and in turn conveyed to man. The energetic glossina, it appears, is able to pierce the skin of the crocodile between the joints of an armour that is impenetrable to an ordinary rifle bullet. The outcome of these investigations is likely to have a vast influence in the future of Central Africa. At present we are able to make an exact diagnosis of the malady of sleeping sickness, and further, thanks to an English medical man, to cure it by injections of atoxyl. It is obviously impossible, moreover, to exterminate the disease by medical treatment alone. It seems equally out of the question to hope to rid a continent of an insect of the wide distribution of the glossina. The logical plan is to attack the crocodiles, and that plan has already been experimented on by Professor Koch. In any case, the crocodile is a creature incompatible with modern civilisation. At the same time, it must be admitted that the reptile undoubtedly serves a useful purpose as a scavenger of African rivers.

A Sea Water "Cure."

OF late a good deal has been heard of a system of treatment of various diseases by the injection of sea water subcutaneously. There may or may not be virtue in the method—that point must be settled by future investigation, but there can be no doubt whatever in the minds of medical men on this side of the Channel as to the undesirable way in which publicity has been given to the system. All kinds of sensational statements have been made as to the results obtained by the discoverer, Dr. Quinton, and enthusiasts foresee nothing less than a revolution in therapeutics by its application. Amongst other things sea water used in the way indicated is said to act as a specific in eczema and kindred diseases in children, and to yield marvellous results in the early stages of tuberculosis. If those claims be only partially justified Dr. Quinton should earn the gratitude of mankind. In the meantime a serious disaster has attended the treatment in the shape of the death from sepsis of a young German noble, who, much against the wish of his friends, submitted himself to the treatment. An accident of that kind, however, does not necessarily detract from the value of the method, whatever that may be. In these days of manifold new cures, it is well for the man in the street to possess his soul in patience before he parts with his money, and submits his *corpus vile* to the hands of the enthusiastic discoverer who is often, maybe, better described, perhaps, as an experimenter.

A Medical Motor Club.

THE medical men of Vienna, it is reported, have started a kind of Co-operative Automobile Club. The object is not so much social as that of providing some sort of organisation which would place the acquisition of a motor within the reach of medical practitioners on reasonable and convenient terms. One good proposal is that manufacturers should be persuaded to build cars specially suited to the requirements of the medical profession. The general idea of purchase is that a moderate sum should be paid down, and the balance settled by monthly instalments until the whole amount is covered. It is stated that the monthly payments will be actually less than the present cost of hiring a carriage by the month. The club is to have its own garage, and branch garages will be opened in various districts as required. The idea seems so good as to be worthy of serious consideration amongst members of the medical profession here at home. The motor-car has come to stay—of that there can be no doubt—and its place in medical practice is becoming more assured day by day. It has often occurred to us that a little timely co-operation might serve to lighten the burden upon professional shoulders in many directions other than the motor-car.

Consumption in West Wales.

THE average man is apt to get weary of statistics, especially in such diseases as consumption, which he regards more or less as the visitation of God. The following figures from West Wales, however, are calculated to give pause to the most cynical philosopher. They are taken from the last return of the Registrar-General—for 1906—of the death-rate from phthisis in the three counties comprised in the West Wales area, viz., Pembroke, Carmarthen, and Cardigan. It appears that in two out of the three counties the mortality is higher than in 1905, and in the third lower than in the previous year, although higher than in 1901. The following table will make it clear:—

DEATH-RATE FROM PHTHISIS, PER MILLION PERSONS LIVING IN THE COUNTIES OF PEMBROKE, CARMARTHEN, AND CARDIGAN IN THE YEARS 1901—1906.

(From the Registrar-General's Reports.)

County.	1901.	1902.	1903.	1904.	1905.	1906
Pembroke ...	1,298	1,296	1,536	1,326	1459	1,312
Carmarthen	1,681	1,688	1,487	1,641	1,391	1,446
Cardigan ...	2,178	2,478	2,121	2,294	2,112	2,316
England and Wales ...	1,264	1,233	1,203	1,236	1,140	*—

* Not yet published.

It will thus be seen that in Pembrokeshire the mortality is higher than in 1901, in Carmarthenshire lower than in 1901, but higher than in 1905, while in Cardiganshire it has reached a higher point than in either of the preceding years except 1902. The necessity of abundant open-air sanatoria in West Wales is evident. Further, it would be well to impress upon the ratepayer of that part of the municipality the necessity of weeding out tuberculous cows from farms and dairies.

Hammersmith and Lady Health Visitors.

ALTHOUGH our lamentable infantile mortality has been prominently before the public for some years past, it cannot be said that many practical remedies have so far come to the front. Among the most promising proposals has been the appointment of lady health visitors, whose duty it is to visit the households of the poor and to instruct them in the elements of child-nursing and of general wholesomeness of environment. The Borough Council of Hammersmith, however, have been recommended by their private Health Committee to dismiss their lady health visitor, appointed in 1906 at a salary of £100. The reasons for this attitude are not known to us, but they must have been somewhat cogent to have prevailed against various protesting deputations of ratepayers. It is disappointing, moreover, to learn that the suggested abolition of office is supported by the Medical Officer of Health. That gentleman is necessarily aware of the excessive mortality of Hammersmith and of the difficulties attached to sanitary problems in so large a poor population. It would be interesting to know what alternatives he has in his mind for effecting a reduction in infantile mortality. Whatever be the ultimate decision of the Hammersmith Council as regards the lady visitor, it is somewhat comforting to reflect that they can hardly be influenced by the paltry reduction of £100 effected thereby, for the whole world has recently been astounded by the revelation of the stupendous sums of money expended on the local workhouse buildings, which in some respects may, without exaggeration, be called fabulous. Truly modern life is full of sharp contrasts!

The Administration of Anæsthetics for Unqualified Persons.

A somewhat remarkable communication has recently been addressed to the *Morning Leader* by Mr. H. A. Barker, a bonesetter, or person who professes to treat bodily injuries and deformities without the guarantee of a surgical qualification. In the course of a sort of semi-scientific harangue upon displaced semi-lunar cartilage in the knee-joint, occurs the following remarkable passage:—"I have treated many thousands of these cases by purely manipulative measures under anæsthetics, and with almost invariably good and permanent results." Incidentally it may be remarked that any practitioner should be able, in the majority of cases, to obtain good results in the kind of injury in question, but permanency of cure is another matter, and he would be a bold surgeon indeed who would prophesy anything of the kind, short of tethering the cartilage to the bone or other radical operation. The question we should like to raise is whether Mr. Barker has the temerity to administer anæsthetics himself or by the aid of an assistant? If he be his own administrator then he exposes his patient to risks that it is not pleasant to contemplate, to say nothing of his own position in the case of an anæsthetic death. If his assistant be unqualified, a charge of manslaughter is not an altogether improbable contingency. Lastly, if his administrator be a qualified medical man—but, even in view of the fact that registered practitioners have recently been found administering anæsthetics for unqualified dentists, we should refuse to believe without absolute and overwhelming proof that such a thing could happen in the case of bonesetters.

PERSONAL.

H.R.H. Princess Henry of Battenberg opened the new children's block of the Rugby Hospital on October 26th.

The Sultan of Turkey has conferred on Sir A. Conan Doyle the Second Class Order of the Medjedieh.

Dr. John H. Dauber has been elected President of the Chelsea Clinical Society for this year.

Dr. George Carpenter has been elected Chairman of the Council of the Society for the Study of Disease in Children.

The Merchant Taylors Company have given a donation of 30 guineas to the Samaritan Free Hospital for Women.

Dr. C. F. Bryan, of Leicester, has been elected President of the Association of Certifying Factory Surgeons for the ensuing year.

Her Excellency Lady Aberdeen has sent a letter to certain general hospitals suggesting the formation of tuberculosis dispensaries in Ireland.

Mr. John Lentaigne, Vice-President of the Royal College of Surgeons in Ireland, has been appointed a Member of the Board of Superintendence of the Dublin Hospitals.

Sir James Barr, M.D., delivered the Bradshaw Lecture yesterday at the Royal College of Physicians of London, the subject being "The Pleuræ; Pleural Effusion and its Treatment."

Dr. Burton Brown, President of the Therapeutical and Pharmaceutical Section of the Royal Society of Medicine, took the chair at the first meeting of that section on October 22nd.

Professor Sherrington, of Liverpool, delivered the inaugural lecture to the Royal Medical Society of Edinburgh at the opening of its 171st session. Dr. A. M. Drennan, President, was in the chair.

Dr. John Carswell, of Glasgow, has been presented with a handsome testimonial and a cheque for £415 by a large number of friends in recognition of his services to the town.

Dr. E. M. Grace, the County Coroner of Gloucester and brother of the famous cricketer, was last week married to Miss Brain, daughter of the late Mr. James Brain, of Cardiff.

The Rt. Hon. Sir Herbert Maxwell, Bart., F.R.S., has been elected Chairman of the Council of the National Association for the Prevention of Consumption. Dr. C. Theodore Williams, M.V.O., has been elected Vice-Chairman.

A meeting of the Board of Management of the Manchester Royal Infirmary was held on October 29th. The retirement of Dr. Mould was announced. Dr. Mould entered the service of the Infirmary at the Cheadle Hospital 45 years ago, and had been constantly associated with the work ever since.

Sir Alfred Keogh, K.C.B., will address a meeting of hospital physicians and surgeons at the Royal College of Physicians, London, asking for their cooperation in working the Territorial Army Medical Scheme. Sir R. Douglas Powell will be in the chair.

A Clinical Lecture
ON
A CASE OF TRAUMATIC EPILEPSY TREATED BY OPERATION.

By THOMAS SINCLAIR,

Professor of Surgery in Queen's College, and Surgeon to the Royal Victoria Hospital, Belfast.

Gentlemen,—The patient before you illustrates the effects of the deliberate removal of a portion of the motor area of the brain in the treatment of traumatic epilepsy—the proceeding sometimes designated Horsley's operation of excision of the epileptogenic centres. It is now more than a year since the operation was performed, and no recurrence of the epileptic fits has taken place. Moreover, the patient is now able to work, and is eager and willing to do so, though during the prevalence of the fits he was incapable of exerting himself with any resolution or continuity of purpose, mentally or bodily.

The personal history shows that the patient was a healthy man, of regular habits, and æt. 33 at the time of the accident in October, 1903. He was struck on the left side of his head by a heavy falling plank. He was unconscious for 27 hours. There were no surface signs of cranial damage, and he left the infirmary, where he had been first treated after a stay of five weeks, fairly well, only a tender spot over the left parietal bone remaining.

After several weeks he was admitted to the Royal Victoria Hospital, having developed the following symptoms:—Insomnia, general weakness, frontal headache, dizziness, very frequent vomiting, and night sweats. Under treatment by rest and bromides the vomiting ceased, and the headache and insomnia had so much improved that he left hospital in three weeks.

Relapses occurred at short intervals during the ensuing eight months, and marked tremor of leg, arm, and tongue appeared, associated with much muscular feebleness, but without atrophy or rigidity. By the autumn of 1904 this amounted to right hemiplegia, and he could neither stand nor walk. In October, 1904, on rising from a chair he had a fit. He fell, and was unconscious; his eyes twisted up towards the left, twitchings, commencing in the right leg and arm, developed, followed by stupor, lasting for two hours. He had no warning sensation or aura. The fits occurred daily for two months, and to a great extent replaced the vomiting of the former time. He declined operation, which was urged, at this stage. Gradually the fits lessened, and so much improvement in the hemiplegia followed that he became able to stand and walk, but he still dragged the right foot markedly. Some trophic changes arose in the right knee, which moved stiffly, with much noisy intra-articular crackling; and his teeth, previously sound, underwent rapid decay. He had nine of them extracted during the next year. In January, 1906, he complained of constant vertical headache; the vomiting and fits were less frequent, he ate and slept well, his hearing, vision, and general sensation were good, and there were no oculo-motor or facial symptoms. His left pupil was larger than the right, and the left optic disc was hyperæmic. His knee jerks were exaggerated, but there were no ankle clonus, atrophy or contractures. He dragged the right foot considerably, but could walk fairly without stick or support. The tremor was then much abated, but still noticeable in the right hand. No urinary symptoms ever arose, and the pulse and temperature were normal.

The propriety of subjecting him to operation at this late stage, and in the face of some amelioration of his symptoms, was debated, but ultimately it was undertaken, on the ground that no further improvement was in progress, and the constant severe headache, tremor, and dejection rendered him quite unfit for any duty. Accordingly, in February, 1906, a large disc of bone was raised over the leg and arm centres on the left side of the brain. No fracture or thickening of the bone existed, and the dura mater showed no pachymeningitis, nor was there any arachnoidal bloodcyst or false membrane to be found. The cortex was discoloured over a small area, and contained some old blood clot, the pia mater was tougher and more adherent, and the density of the cortical area involved was firmer than natural. An exploration through and around this area was made in order to exclude the presence of abscess or underlying cyst, and finally a portion of the cortex, about the size of half-a-crown and nearly half an inch in depth, was excised. The disc of bone was re-implanted, contrary to Kocher's advice, and a perfect restoration of the cranial vault was obtained, after a normal healing, without drainage. The headache ceased almost immediately, and the other symptoms underwent rapid improvement: even the artificial hemiplegia caused by the excision of the convolutions passed off in a few weeks. So encouraged was the patient, that one had to restrain him from a too early resumption of work, which is unwise in these head cases after trephining operations. For a kindred reason the clinical demonstration to you of the result has been postponed for a year or more in order that the permanence of the improvement may be better ascertained and attested.

In analysing the symptoms before operation, to frame a diagnosis, it appeared probable, from the up-and-down character of these, that the cortical irritant was not of a bony nature, either osteitis or fracture of the internal table, which, it must be remembered, can occur without obvious change in the outer table of the skull. The likelihood of a small cortical abscess having formed was also not manifest, unless the night sweats of the early period might appear to suggest it. These perspirations lasted only a few weeks, and were not associated with the subnormal temperature and emaciation generally found in suppurative conditions of the cerebrum. Moreover, an abscess, though it may lie dormant for months, when it begins to cause irritative signs advances from irritation and convulsions to greater compression and coma. The improvement in the hemiplegia seemed inconsistent with the theory of abscess. On the whole, an arachnoidal blood cyst adherent to the brain in the motor area, or a blood clot in a contused cortical area associated with variations in the local circulation from time to time, appeared the most probable construction to place upon the clinical signs. The latter condition was found at the operation, and a degree of condensation or sclerosis with adhesion of the pia mater, resulting from a local non-suppurating cerebritis in the involved area, had evidently followed the original damage. That this damage, contusion, or laceration, had been considerable was clear from the long duration of the so-called concussion signs at the beginning, extending the unconsciousness to 27 hours, as already noted. It was this patch which was extirpated at the operation.

In traumatic, or Jacksonian, epilepsy with local symptoms, the earlier the operation is carried out the better, for the longer the fits have lasted the more likely are they to become habitual and approach the status epilepticus; hence the condition becomes less amenable to treatment as time wears on. The prognosis should not be too sanguine as regards the epilepsy, even in apparently favourable operation cases. A probationary period of at least one year should elapse after an operation before an estimate is formed of the result, for experience shows that there are numerous cases of relapse and consequent disappointment in this branch of surgery. Even the contraction of the cerebral scar, which necessarily forms after an excision like the one above described, has to be reckoned with as potent for mischief in this regard.

The possibility of supplying a bony irritant by the re-implantation of the bone disc must not be lost sight of in epileptic cases. Kocher says it is best, as a general rule, not to re-insert the disc, or fragments of bone, as grafts in these cases. The harsh edges presented to the brain by fragments or tilting of the disc may readily reproduce the convulsions. Certainly the practice of re-insertion should be avoided when the undersurface of the disc is irregular from fracture or osteitis, or when it cannot be adjusted flush with the surrounding vault for want of a good foundation. In the present instance, the conditions being all favourable, the re-implantation was adopted, and for so far there appears to be no cause for regret. Finally, it may be advised that patients who have been operated upon for epilepsy should not be allowed to engage in laborious work involving stooping, worry, or excitement for many months, no matter how gratifying the immediate results may appear.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Edred M. Corner, B.Sc.Lond., M.C. Cantab., F.R.C.S., Surgeon in Charge of Out-Patients St. Thomas's Hospital; Senior Assistant Surgeon, Hospital for Sick Children. Subject: "Deformities of the Foot Associated with Abduction."*

A Supreme Health Authority.

IT is proposed to hold a conference of representatives of sanitary authorities in London to consider the question of the establishment of a permanent union of sanitary authorities of the United Kingdom. The Court of Common Council of the City, at its meeting last week, asked the following gentlemen to represent the Corporation:—Mr. S. Pollitzer (the Chairman of the Sanitary Committee), Mr. H. F. Hepburn (the late Chairman), the Medical Officer of Health for the City, Mr. H. S. Dove (the Chairman of the Port Sanitary Committee), Mr. R. Stapley, J.P. (the late Chairman), and the Medical Officer of the Port of London.

A CASE of smallpox has been notified to the ambulance department of the Metropolitan Asylums Board from St. Pancras and removed to the hospital.

ORIGINAL PAPERS.

ABSTRACT OF

THE BRADSHAW LECTURE

ON

THE PLEURA; PLEURAL EFFUSION AND ITS TREATMENT. (a)

By SIR JAMES BARR, M.D., LL.D., F.R.C.P., F.R.S.E.,

Senior Physician, Liverpool Royal Infirmary; Visiting Physician, Haydock Lodge and Tuebrook Asylums.

THE first part of the lecture dealt fully with the anatomy and physiology of the pleura, with the important question of intrapleural, intrathoracic and intrapulmonary pressure. After an exhaustive consideration of ætiology and diagnosis, the learned lecturer proceeded: In the treatment of pleural effusion the question often arises when should you withdraw serum? Effusion is a natural process which, if it continue till after the inflammation has subsided, lessens the risk of pleuritic adhesions; it also keeps the collapsed lung quiet, which is very desirable if there be any active tuberculosis in the lung. A large proportion of cases of pleurisy are tubercular, and the early withdrawal of fluid causes vascular turgesence of the lung, often hastens the dissemination of the tubercle bacilli, and kills the patient. Before I began the substitution of one fluid for another by the introduction of air into the pleural cavity, I was much more chary about early tapping than I am at present. I can now remove the whole of the effusion, even in tubercular cases, at an early stage, with perfect impunity. A considerable number of deaths have followed the complete withdrawal of effusion in elderly persons with rigid chest walls. The danger in such cases arises from establishing too great a negative pressure, which leads to hyperæmia and œdema of both lungs; this can be obviated by the introduction of air. I now recommend the complete withdrawal of the effusion in all cases, but before any great negative pressure is established, and before the patient feels any discomfort, I stop the siphon and introduce about an equal quantity of air to the amount of fluid which I have withdrawn. I then re-establish the siphon, and complete the withdrawal of the effusion. When all the liquid is withdrawn I inject four cubic centimetres of adrenalin solution (1 in 1,000), diluted with eight or ten cc. of sterile normal saline; and if I think it necessary I introduce more sterile air, so as to make the total amount equal to a half or three-fourths of the bulk of the fluid withdrawn; the larger quantity of air is introduced in tubercular cases. By this method the patient suffers no discomfort, except from the slight thrust of the trocar. I prefer the siphon to the aspirator, because you can readily regulate the force of the suction, and as your tube only reaches to a receptacle on the floor, practically your negative pressure never exceeds one pound to the square inch; this force is greatly exceeded by the aspirator, and the greater the negative pressure the greater the risk of secondary hyperæmia and œdema. It is an advantage to introduce a manometer in the air tube, as you can thus avoid producing any positive pressure in the pleura. Of course all aseptic precautions are taken.

The adrenalin solution is introduced to contract the blood-vessels and lessen the secretion. According to Schäfer, Elliott, Brodie and Dixon, adrenalin only acts on unstripped muscular fibre which is innervated by the sympathetic; the pleural vessels belong to the systemic system and are thus innervated, but its effect is not very prolonged; consequently you cannot expect it to lessen the secretion for any great length of time if there be a great negative pressure in the pleura. Although I had good success from its use, before I commenced the introduction of air, I soon recognised the limits of its usefulness. When you remove four or five pints of serous fluid from the pleura, there is a potential or actual cavity left which cannot be filled by a drachm of any fluid. Such a cavity cannot exist in the human body with a surrounding atmospheric pressure of 15 lb. to the square inch. It is filled by—(*a*) the carbonic acid gas which escapes from the serous fluid; (*b*) by the more or less expansion of the collapsed lung; (*c*) by the return of the mediastinal contents, which were pushed or drawn to one side, and the further expansion of the other lung; (*d*) by increased quantity of blood in the chest; (*e*) by elevation of the diaphragm, and (*f*) by falling in of the chest wall. All these events may not suffice to fill the cavity if the amount of fluid withdrawn has been very great, and the lung so collapsed and bound down that it cannot expand. In this case the negative pressure is very great, and under such circumstances it would be absurd to expect adrenalin or anything else to permanently check the secretion. When the use of adrenalin is supplemented by the introduction of air, the negative pressure is lessened or abolished, and the lung gradually expands as the air gets absorbed. By this combined method you can operate early in any case even during the febrile stage, and under no circumstances should you allow the fluid to accumulate to such an extent as to completely collapse the lung; you should tap before the patient suffers any respiratory distress. By the removal of the effusion you often remove an enormous number of micro-organisms, and by the introduction of sterile air you substitute a light, innocuous fluid for a heavy and deleterious one.

(a) Delivered at the Royal College of Physicians of London Nov. 5th, 1907.

Dr. W. Ewart, of London, has recently been injecting adrenalin solution into the pleural fluid preparatory to drawing it off, and he has had good success in thus stimulating the absorption of the effused fluid.

When the pleurisy is practically cured, you will find plenty of scope for ingenuity in trying to restore the function of the lung to its pristine vigour. I have no time to enter into the numerous respiratory exercises which I from time to time recommend, but there is one which each of you can now try on himself—the marked effect of throwing one serratus magnus muscle into, and the other out of, action. The function of a physician used to consist in prescribing drugs and giving some directions about diet, but fortunately these days have passed for ever. I have not told you anything about drugs, though I am a firm believer in their efficacy when appropriately used, as I have not got any specifics for pleural effusion. There is one drug, common salt, which you should as far as possible eliminate from the diet, especially in cases of sero-fibrinous pleurisy on account of its high osmotic equivalent. When you hear men telling you that they gave 10 minims of something or other three times a day, and the fluid disappeared as if by magic, you can envy such credulity, but it is impossible to admire it.

When there is a large quantity of effused fibrin, such as occurs in pneumococcal pleurisy, decalcifying agents such as lemons, citric acid, the citrates of ammonium, potassium, and sodium may be used.

I shall now give you a short account of the history of the introduction of adrenalim and air into the pleural cavity. In August, 1902, I saw regularly, in consultation with Dr. Chisholm, Mr. F. T. Paul, and Mr. R. A. Bickersteith, a lady who was suffering from secondary cancerous deposits in the pleura with effusion. The fluid had to be withdrawn every four days, and it re-accumulated so quickly that she had scarcely a day free from distress in breathing between the aspirations, and I saw that this state of matters could not continue long. Necessity is the mother of invention, and I began to consider how to lessen this secretion. I came to the conclusion to try an injection into the pleura of suprarenal extract, and I fixed upon Parke, Davis and Co.'s adrenalin chloride, 1 in 1,000, as being a sterile preparation. I empirically fixed one drachm or 4 c.cm. as the amount to be injected, and after the fifth aspiration this quantity was used. There was no further secretion, consequently no further tapping, and the old lady spent the remainder of her life in perfect comfort, so far as the chest was concerned. In her memory her husband contributed £12,000 to establish the Liverpool Cancer Research Fund.

Since this case I have injected one drachm of adrenalin solution into every pleura which I tapped, and in only two cases have I had to draw off the fluid a second time. Soon after I began this method—to which no one has laid any prior claim—I commenced, in addition, the introduction of sterilized air to replace the fluid which I had withdrawn. I was led to adopt this procedure by the distress frequently caused to the patient by any attempt to withdraw all the serum; by the usually rapid re-accumulation, especially when there was any negative pressure left in the pleura, or there was a large potential or actual cavity owing to the lung being so collapsed or bound down that it could not expand; by the great risk of collateral hyperæmia and œdema of one or both lungs, especially in those persons with rigid chest-walls; and by the fact that in tubercular cases there is apt to be a rapid dissemination of tubercle through the lung when the pleural pressure is removed. As four-fifths of the air is nitrogen, which is only slowly absorbed, this air pad tends to prevent or lessen pleural adhesions. Since I began the substitution of air for serum I have been able to withdraw the whole of the liquid with perfect impunity.

I exhibited my first and second apparatus for the introduction of adrenalin and air into serous cavities at the Liverpool Medical Institution on November 5th, 1903; and the following week there was a notice of my apparatus in the proceedings of the Medical Institution published in the weekly medical journals.

In the *British Medical Journal* of March 19th, 1904, I published a Clinical Lecture on the Treatment of Serous Effusions, in which I fully described my method and apparatus for treating effusions into all the serous cavities. At that time the idea of injecting sterilized air was quite original, so far as I was concerned, and some of the leading members of the medical profession to whom I spoke on the subject had never heard of any such practice, but I afterwards found that some others, to whose writings I shall presently refer, had been in the field before me.

In the *Edinburgh Medical Journal* of November, 1886, Dr. Theobald A. Palm published an account of three cases where he allowed air to be sucked into the pleural cavity after aspiration. One case recovered after one tapping, another after two, and the third "case took an unfavourable course, and in the course of some months the patient died."

On April 24th, 1888, M. Potain communicated to the Academy of Medicine, Paris, a successful case of pyopneumothorax treated by the injection of sterilized air after the removal of the liquid. His object was to keep the lung compressed until the pleura-pulmonary fistulæ had healed, and to prevent the reproduction of the liquid.

In Italy several papers appeared between 1888 and 1902 on the introduction of air into the pleural cavity by Drs. G. Lava, G. Cavallero, S. Riva-Rocci, and Professor Forlanini.

About or before 1900, Professor Ayerza and his pupil, Dr. Bungé, of Buenos Aires, treated cases of acute and chronic tubercular pleurisies by the abstraction of the liquid and the injection of oxygen gas. They used oxygen as a specific medication against the tubercle bacilli, but as oxygen is more readily absorbed than nitrogen, in no case did the pneumothorax last longer than 14 days. Recently Professor Forlanini has advocated the treatment of phthisis by the repeated introduction of oxygen gas into the pleural cavity, so as to maintain an artificial pneumothorax and thus rest the lung. About a century ago a somewhat similar treatment of phthisis was carried out in Liverpool by the late Dr. Carson and Mr. Robert Bickersteth. They produced a pneumothorax by an external opening into the pleura, but they soon gave over the practice.

In addition to cases in foreign literature, there is in the *Lancet*, November 10th, a reference to a case reported at a meeting of the Société Médicale des Hopitaux de Paris, on October 12th, 1906, by M. Dufour and M. Foix. They successfully removed a large chronic pleural effusion and injected sterile air.

This systematic treatment of pleural effusion by the combined method of the complete withdrawal of the liquid, and the introduction into the pleural sac of adrenalin and sterile air which I may fairly claim to have originated, will, I hope, be more appreciated as it becomes better known. The adrenalin solution is better diluted with two or three times its bulk of normal saline solution.

EMPYEMA.

This is one of those numerous diseases which the surgeons have taken under their own special care, and they have done nothing to advance its treatment, I presume because physics seem to have formed no part of their education. In the case of a child with elastic chest-walls you could not easily mismanage a case of empyema. A considerable number of cases get well in spite of treatment. When a surgeon has to deal with a purulent effusion in the chest, about the only idea which he can get into his head is free drainage, and forthwith out comes a piece of rib and in goes a large drainage tube, expecting it to suck up the liquid from the most to perhaps the least dependent part of the cavity, and utterly reckless as to whether the collapsed lung ever expands again or not. Dr. Otto Grünbaum has devised a useful appliance for assisting the lung to expand in these mismanaged cases, but I do not know of any surgeon who has taken it up. Mr. Arthur Edmunds, to whose valuable work I have previously referred, insists on the anæsthesia being very light when operating on an empyema, so as not to abolish the pleuro-laryngeal reflex, and thus the vocal cords are enabled to play their part in maintaining the pressure within the lungs.

If I were a surgeon, and had to deal with such a case, I would use a local anæsthetic, such as eucaine; or, if thought necessary in any particular case, light general anæsthesia as recommended by Mr. Arthur Edmunds. I would make a free incision in a very dependent spot, about the eighth or ninth intercostal space, in a line with the lower angle of the scapula. If the ribs were close together it would be well to take out a long piece of one rib, and then make a free incision into the pleura. An assistant should firmly compress the side so as to drive the purulent matter out, and allow as little air as possible to enter the chest during the operation. A strip of gauze may be inserted in the wound to keep it open, but no tube should be introduced. I would then apply a large piece of sterile oiled silk over the wound to act as a valve, so as to allow the fluid to escape, and no air to enter. Large aseptic dressings should be applied over the valve. The affected side may be well strapped to prevent movement. I would make the patient lie on or towards the affected side, so as to lessen movement and encourage drainage, prevent him taking any deep inspirations, and tell him to take deep nasal expirations, so as to expand the affected lung, and drive the purulent fluid out of the cavity. He should be instructed to inspire through the mouth and expire through the nose. I would also make him frequently practise the Valsalva method, or blow through a small tube. If the pus be very offensive, or not draining well, the patient can be treated in a continuous bath, and then no dressings will be required.

In these cases the pus is usually fairly fluid, is neutral, or may even be slightly acid in reaction, contains some peptone and a ferment which seems to have the power of digesting fibrin, and thus the lung is not likely to be irreparably collapsed or bound down by adhesions; there is therefore a fair chance of success if the operation be adopted early, and the after treatment intelligently carried out.

The variety of micro-organisms in the pus should be ascertained, and an appropriate vaccine, after the method of Sir A. E. Wright, should be used. Even the stinking empyemata from the bacillus coli often do very well. Tubercular cases are the most troublesome, and usually when the fluid becomes purulent there is a mixed infection. Cases of pyo-pneumothorax are best treated by drawing off the fluid and filling the cavity with sterile air or oxygen. Where the empyema is loculated the surgeon may remove a piece of rib if he choose; he cannot do much harm. Unfortunately Estlander's operation is often necessary, partly owing to early mismanagement of the cases. There must be some effort made to place the treatment of this disease on a more scientific basis than that on which it at present stands.

I have spoken strongly about the surgeons, because I feel strongly, and I am anxious that they should remove this blur from their fair escutcheon. The old wheeze about the physicians not handing the cases over soon enough is now played out. There is still, however, plenty of work for the physicians; prevention is better than cure, and I think in the future their work should lie more and more in that direction. Our aim should be to protect the individual from the ravages of disease and the onslaught of the surgeon, and make the very existence of that individual less and less of a necessity.

DEATH FROM HÆMORRHAGE FROM A MEDICO-LEGAL POINT OF VIEW.

By PROFESSOR HENDRICK, M.D.,
Of Hamburg.

PART I.

DEATH from hæmorrhage takes place when, in consequence of a solution of continuity at any particular part of the body, such a large quantity of blood is withdrawn that the amount left in does not suffice to carry the necessary amount of oxygen to support life to the various organs, especially the brain.

The quantity of blood lost necessary to cause death from hæmorrhage bears no relation to the amount in the whole system, but is dependent first upon age; the relative quantity of blood the loss of which could be borne by adults without injury to health will kill a child. Secondly, on the general condition of the individual. Persons of weakly constitution, especially with a diseased condition of blood—such as often comes on after exhausting diseases—as well as those with pulmonary and cardiac diseases, which hinder oxydation of the blood and the rapid blood supply of the body, bleed to death more rapidly than healthy individuals. In such cases a disease accompanied by hæmorrhage will result in death, when it would not under normal circumstances. Thirdly, the loss of blood necessary to cause death is dependent on the kind of blood lost, whether arterial or venous. Arterial blood contains nutrient material indispensable to the life of the tissues (oxygen); venous, on the other hand, contains the cast-off materials of the tissues (carbonic acid). It is at once clear that the body bears a loss of venous blood better than that from an artery. Fourthly, the amount of loss required to cause death depends on the length of time the bleeding lasts, whether it is rapid and continuous, or whether there are interruptions of hours or days. This, as the experiments of Juergenson have shown, is explained by the fact that a loss of blood is quickly compensated by reflux of lymph out of the tissues, and so when the bleeding is interrupted, a substitute for the lost blood takes its place, and so losses with interruptions are borne when without a break they would be fatal. In this way a man may gradually lose a quantity greater than the whole quantity originally present in the body.

In general it may be said: To bring about death from hæmorrhage, the loss of a very considerable part of the whole of the blood of the body is necessary; the loss of half of it causes death in most cases; the loss of still greater quantities does so with certainty (Oesterlen). Experiments on dogs on bleeding have shown: dogs survive a loss of blood when 4 per cent. of the body weight, = 52 per cent. of the whole quantity of blood, is withdrawn; they die with a loss of blood of 5.5-6 per cent., = 64-72 per cent. of the total amount of blood. To bring forward decided figures, Seydel, amongst more recent authors, gives a loss of 1,500-1,800 grammes as the average amount that would prove fatal for a medium-sized man. Börnträger and Berg give 1,800 ccm. as a mean for internal hæmorrhage. There are variations from 1,500-3,000, but extremes are rare. Casper-Liman consider it idle to fix the amount necessary to cause death for medico-legal purposes, however interesting for physiology. It is not so important in practice to determine the amount of blood accurately as one would at first think, as the quantity of blood comes into question diagnostically only in internal hæmorrhage; in external hæmorrhages the amount cannot be measured.

The diagnosis of death from hæmorrhage may sometimes be determined before the body is opened on the evidence of unbiassed witnesses who have witnessed the occurrence. The symptoms under which death takes place from external hæmorrhage under ordinary circumstances are the following: A large stream of blood spurts out of the wound, the wounded man sinks with a cry to the ground, a pallor spreads over the features, the tongue becomes pointed, the breathing stertorous, the limbs cold; the sufferer throws his limbs about, then clonic convulsions supervene, and at last death. In such a case a post-mortem examination only confirms the diagnosis already made. In other cases in which eye-witnesses have not been present, but the body has been found some time after the death has taken place, when it has taken place from external hæmorrhage, numerous traces will lead to a diagnosis. The blood may lie in great pools upon the floor, or it may have sunk into the soft soil; it may have spurted against walls or other objects; the clothes may be soaked through, or the blood may have run down the body. The forensic surgeon must carefully note all traces, and from them estimate the amount lost. For this it may be necessary to examine the soil, the clothes, and other objects as regards saturation, if the blood is dried in. However, the quantity of blood that has escaped, as has been mentioned, can only be imperfectly estimated. Moreover, it has to be considered that the blood may have been washed away; the body may have been removed from the place where the death took place; and in this way all traces of blood may have been lost. In such cases, as in all cases of death from internal hæmorrhage, the diagnosis can only be made from what is seen on opening the body. The findings on doing this are the following: The skin is a waxy white; Seydel describes it as a whitish yellow; the colour of the mucous membranes of the lips and conjunctivæ is almost white. According to Caspar-Liman, exceptions to the waxy white colour are not infrequent ("cases are not rare where a practised observer would not think of death from hæmorrhage, the colour of the body being quite the usual one"). One result of the skin being empty of blood is the imperfect formation of discoloured patches; they may be absent altogether.

Views differ on this point. According to Divergie (quoting from Sachs), the death patches are always absent, whilst Maschka and Caspar-Liman describe them as rarely so. Hoffmann saw them repeatedly; Chlumsky had the opportunity of noting their absence on three successive days after death. He remarks that Divergie's case is not conclusive; it is not stated at what time after death the autopsy was made, and whether it was not before hypostasis could have taken place. Börnträger and Berg describe the total absence of discolourations as rare. Seydel speaks of slight patches. If, with Sachs, one draws the actual conclusions from these various views, we come to the following as regards the patches: (*a*) hypostasis is slow in the bodies of those who have bled to death; (*b*) in rare cases the discolourations may be absent altogether; (*c*) the patches are smaller and paler. Rigor mortis in these cases does not differ from the ordinary.

Examination of the body internally shows general anæmia of the vessels and parenchymatous organs in a varied but always high degree (Oesterlen). We should not look upon the bloodlessness as if every drop of blood had left the body, as the quantity that has escaped depends, as already mentioned, on a number of factors. Börnträger and Berg also, in their latest work on the subject, remind us that we must not expect a complete emptying of the body. It has also often been shown by experiments on animals that in deaths from hæmorrhage all the blood does not leave the organs. All the larger venous trunks are bloodless, or at least show a want of blood; but it is to be noted that the veins of the pia mater from gravity are rarely empty, but generally visibly filled. Caspar-Liman give a special warning not to doubt from this fact that death has been the result of hæmorrhage. The cavities of the heart are generally empty, but they may contain a small quantity of blood. It is rarely that the so-called sub-endocardial ecchymoses are absent (Hofmann, Puppe). The paleness of the mucous surfaces of the œsophagus, stomach, intestines, and trachea, amounting to a whitish yellow, is very pronounced. The quantity of blood in the glandular organs varies. The lungs and brain show remarkably little blood, the spleen and liver are generally very pale, whilst the kidneys often show a considerable quantity. On section the organs are dry. The lungs are gray in colour, the brain yellowish white, the spleen a pale reddish, the kidneys are from a clear grey-red to clear grey, the liver pale brown if pigmented, or pale yellow if fatty.

The general absence of blood, however, is not an absolutely certain sign of death from hæmorrhage, as even when pronounced, it may be found in the bodies of those who during life have suffered from poorness of blood, conditions of lingering exhaustion, from tuberculosis, malignant tumours, or long-continued suppurations. In the latter cases accompanying symptoms—dropsy, emaciation, decubitus—will appear, whilst on the other hand the source of the bleeding is conclusive as regards diagnosis. Further, general bloodlessness is met with in bodies in which decomposition has taken place, in which, in consequence of putrefaction and permeability of the vessels, the blood has trickled through and left the vessels, or has evaporated, whereby diagnosis is rendered more difficult.

Death from hæmorrhage may therefore be assumed when signs of internal or external bleeding are present, and a solution of continuity in the vessels is seen as the source of the hæmorrhage, the latter with the limitation that, according to Caspar-Liman, the discovery of the source of the hæmorrhage is not always possible in internal hæmorrhage, and therefore not always necessary; further, if the above described general bloodlessness is present, the body is not decomposed, and all other causes of death are excluded.

The following forms of death from hæmorrhage are distinguished: It may be from internal or external bleeding; it may be acute and uninterrupted; or it may take hours; it may have intermissions of days (aneurysm 66, self-help or aid from others, anatomical conditions); it may follow direct from the injury or after the lapse of some time from an intercurrent cause (suppuration, development of aneurysm), and therefore be mediate. The solution of continuity causing it may be spontaneous from morbid changes in the organ, or from only slight violence, or when the organ is sound from the action of considerable violence; or, finally, it may be from simple loss of blood, or as the result of a secondary action of such loss (paralysis from pressure on the brain, heart, lungs, blocking of the respiratory tract from poured-out blood into the air passages, air embolism). In the latter case we speak of complex death from hæmorrhage. This mode of death borders on that from suffocation, but is reckoned as death from hæmorrhage, but is distinguished from it as complicated "verblutungstod." This distinction, however, is not strictly carried out in the larger text-books (Hofmann, Strassmann). Complicated death from hæmorrhage differs from the simple in important points—cause of death, quantity of blood lost, the amount left in the organs—very considerably, and must therefore be kept distinct from it. Very closely allied, and in reality belonging to it, are those causes of death of persons whose blood is poor in consequence of diseases of the heart, lungs, or of the blood itself. By theoretical conclusions, in the absence of certainty, it must be assumed that in these cases the loss of blood causing death is considerably less than in normal bodies, as paralysis of the brain, the ultimate cause of death, takes place earlier. In such cases death would follow from hæmorrhage—as in abortion—when it would not otherwise. From a purely anatomical point of view death from bleeding from an artery is distinguished from that from a vein. When the bleeding is from an artery the course is quicker than when from a vein. A partial severance of a vessel is more dangerous than a total one, as in the latter case a plug can form readily; a transverse division is more dangerous than a longitudinal one from the gaping of the edges of the wound (Oesterlen).

For the exhaustive treatment of a case of fatal hæmorrhage the forensic surgeon must obtain the clearest possible idea of things from the witnesses, and from the wounds—from the infliction of the wound to the death of the patient. If a person with an external wound is found dead, the surgeon must know, if no other cause of death is evident, whether such a wound could cause fatal hæmorrhage, whether, if such is the case, the blood flowed internally or externally, in order, in the latter case, to search for traces of blood; he must be able to decide whether death has followed immediately from the discovered or suspected cause, or whether some time may have elapsed between the injury and the death, and how long a time, and especially whether the injured man could have performed any action; further, whether the bleeding has been continuous or interrupted, and thus whether death has resulted from primary or secondary or late hæmorrhage, and by what factors this was caused (especially anatomical conditions, the formation of aneurysms, any aid that has been rendered by the deceased himself or by others, the presence of wound infections); further, in case of internal hæmorrhage, when a solution of continuity is found on examination, whether it may be spontaneous, when the morbid cause must be looked for, or whether violence has been inflicted, and the nature of it (traumatic); further, whether the case is one of simple or complicated fatal hæmorrhage, and what condition of body may be expected to be found; then what signs for solving the question as to whether the case is one of murder, suicide, or accident; whether self or any other aid was possible; whether it was given, or whether intentionally or unintentionally omitted; finally, whether and how proof is to be adduced of a causal connection between a death from hæmorrhage and a wound inflicted at an earlier period, especially in cases where survivors will benefit from property left by the deceased.

The various forms of death from hæmorrhage must be considered from these points of view. These, according to Sachs, may be classified in the following manner:—(1) Death from hæmorrhage from solution of continuity of the heart; (2) From solution of continuity of the great vessels, arteries, and veins; (3) From parenchymatous bleeding; (4) From rupture of internal organs; (5) From bleeding to death at birth; (6) From fatal bleeding from the female genital organs.

I.—Death from Hæmorrhage from Solution of Continuity of the Heart.

Death may take place from solution of continuity of the heart in various ways. The simplest is that where the heart receives a stab from without; a great stream of blood gushes out, and the wounded man gives up the ghost in a very short time with the symptoms mentioned above. Friedberg (Gerichtsärtliche Gutachten, Seite 144) draws attention to stretching of the arms upwards (*in die Höhe strecken*), as pathognomonic of wound of the heart. In other cases the wound opening is not free, and the blood escapes inwards into the pericardium, the pleural cavity, a hæmato as well as a pneumothorax is formed, and death may be less rapid.

A third mode is when the bleeding takes place into the pericardium. This occurs when rupture of the heart takes place, and there is no external wound, but it may also occur when punctured wounds of the heart are present, when the pericardial wound does not correspond in position to that of the heart itself. The blood expands the pericardium more and more, a sort of shell forms around the heart, and gradually paralyzes it (Rose's tamponnade). The blood here lost amounts to about 300-600 ccm. Death from hæmorrhage is therefore complicated in these cases by paralysis of the heart. Whether the final cause of death in these is the loss of blood or the paralysis is disputed (Fischer, Frierich, Streifensand, Gerard, Richter, Friedberg). Richter and Placzek have also gone into the question experimentally as to whether death takes place slowly or rapidly, without, however, arriving at any decisive result. A fourth method is that in which the wound of the heart is closed by blood clot, the bleeding ceases, and after a time the clot, which may heal in completely, becomes softened by suppuration, and a late hæmorrhage soon leads to death. The case is therefore one of late bleeding set up by the intermediate cause of suppuration. It may be difficult to prove a connection between this bleeding and the previous injury. Finally, cases of death from wounds of the heart occur where the death cannot be explained by either loss of blood or compression of the heart; general shock or wound of the cardiac ganglia must be taken as the cause (König, *Lehrbuch*, 1885, Bd. I., S. 75). That such nerve injuries can cause death, punctured wounds made by needles show, which kill at once without reaction (König). The amount of blood lost varies, naturally, very much, according to the nature of the nerve injury. In such cases we should have to speak of death from hæmorrhage complicated by paralysis of nerves.

Corresponding to these varieties, of course, the time that elapses after the injury is also very varied; it may be five minutes, or it may be several hours, or even days. Hofmann collected 29 cases of punctured wound of the heart, in which death took place in 50, 24, and 1¼ hours (one case each respectively); in 5 cases after a few minutes; in 13 no time was stated. In a case of wound of the heart reported by Rüth, death took place on the fourth day; Picht mentions a death from punctured wound of the heart after 6 days; Bartikowsky after 1¾ hours; Leonpacher after 3 days. Sachs brings forward a case of punctured incised wound of the anterior wall of the heart where several days elapsed after the injury. The varied interval of time between the injury and death is explained by the varied course, but is not based on it. We are not sufficiently clear as to the precise causes. According to Richter, it may be a question of local causes—the part of the heart affected, the size of the wound, the course of the canal of the wound, the direction in which the muscular fibres are severed, or the form of the wound. In the meantime the special influence of these factors has not yet been established. On the other hand, it might be thought that the clotting power of the blood would have an effect, and it is also to be borne in mind that individual conditions (age, general state of the health, morbid conditions of the heart) would have some influence on the rapidity of death. In late death after wounds, the wounded man may do something whereby the inquiry into the facts may be rendered very difficult. Fischer brings forward a number of such cases ("Die Wunden des Herzboundldes Herzbeutels," *Archiv. f. Klin. Chir.*, Bd. IX., 1868). Richter illustrates these cases very clearly by examples. In one case the medical witnesses denied the possibility of a man with a wound of the heart being able to run through a street, so that the official who was making the inquiry came to the conclusion that the deed was committed at the spot where the body was found, and that something was being kept back on the part of the witnesses. In another case, a suicide, no doubt for the purpose of mystifying, after stabbing himself in the heart, had put the knife into his pocket, whereby naturally the inquiry was rendered much more difficult.

A solution of continuity of the heart may occur spontaneously in diseased organs, or traumatically in healthy ones. The diseases of the heart that lead to spontaneous rupture are, according to Eichhorst, myocarditis and its sequelæ, abscess of the heart (acute and chronic), cardiac aneurysms, valvular disease, diseases of the cardiac orifices, the main vascular trunks, of the coronary arteries, new growths, and echinococci in the muscles of the heart. Meyer (Virchow-Hirsch, 1888, II. Bd., S. 172) has collected 24 cases of cardiac rupture, and as the most frequent cause of it has found: narrowing or closure of the coronary arteries (descending branch of the left coronary artery). The consequence of these are patches of softening of the muscles of the heart, hæmorrhagic infarcts, with sudden blocking of the blood supply, fatty degeneration of the myocardium, with gradual closure, wheal-like cicatrices after the healing of infarcts, most frequently on the lower part of the left ventricle. If the heart is changed in this way, rupture may unexpectedly take place as a natural consequence of the progress of the pathological condition, or slight bodily or mental disturbance may be required. As such have been observed: the lifting of a weight, a fatiguing dance, cold water bathing, straining at stool, too full a meal, coition, epileptic attacks, the bolting of a big piece of meat. In the same way, naturally, the slightest external violence may cause a diseased heart to rupture. According to Drenckhahn's collection, the slightest observed traumatic causes have been a kick, or a blow of the fist. Elten rightly says, "Spontaneous and traumatic ruptures of the heart in cases of degeneration of the muscles of the heart pass immediately into one another." To decide whether a case is one of traumatic or spontaneous rupture, the following diagnostic aids must be made use of: Experience has shown that the right auricle is most exposed to rupture, whilst spontaneous ruptures there show where the cardiac diseases present are the most readily developed. According to Klein the rent in spontaneous rupture of the heart is mostly small, jagged, the margins infiltrated with blood, with fatty degeneration in the immediate surroundings. In traumatic rupture the opening is smooth and large; the margins show no sanguineous infiltration, and there is no adjacent myomalacia. The solutions of continuity of the heart produced traumatically, like those of the blood vessels and organs generally, are caused by stabs incised, and gunshot wounds, or a blunt force (falls from a height, being run over, crushing between two fixed or moving objects—for example, the buffers of railway wagons—a blcw, push, or fall). They become the object of medico-legal inquiry, as grave bodily injury, murder, suicide, and in the form of the daily occurring accidents of all sorts (Sachs). The implements that come into consideration in such cases are the incising, stabbing, gunshot implements in general use. That with such gross violence to the heart it happens occasionally that there are no marked external signs of injury is shown by an interesting case (*Zeitschr. f. Med. Beamte*, 1899, No. 16), where a four-year-old healthy child fell from a wagon, struck the fore part of its body, and died in 20 minutes. At the autopsy there were only skin abrasions over the eighth and ninth ribs of the left side, and on the hips, whilst 120 ccm. of blood were present in the pericardium, partly clotted and partly fluid, and a large opening 11 cm. in length in the right ventricle.

On having to decide whether a case is one of murder or suicide in punctured wounds of the heart, conclusions may be drawn from the course of the wound. A perfectly horizontal course is in favour of murder (Maschka). The direction from above downwards is rather in favour of design than accident. Caspar-Liman mention a case in which, from the course of the wound, the question could be answered whether the deceased was stabbed or whether, as declared by the accused, he ran on to the knife.

(*To be continued.*)

RECUMBENCY IN THE TREATMENT OF INFANTILE PARALYSIS.

By ADONIRAM B. JUDSON, M.D.

In the ever-changing treatment of disease the influence of environment is receiving unusual attention, as is seen in the management of tuberculosis of the joints. The influence of the lapse of time is also better understood. Medicines are given in small doses for very long periods and the effects of time on the body are more clearly seen to influence the course of disease and the action of remedies.

In the treatment of infantile paralysis I propose a method which relies exclusively on the influences of environment and the lapse of time. It is applicable only in the very early stage, before the case is likely to be seen by an orthopædic surgeon. As soon as the disease is recognised I would limit the patient to the recumbent position till there is no possibility of further recession of the paralysis. The period of spontaneous recession extends over several months. During this time the difficult task must be undertaken of keeping a child, well in every other way, off his feet at an age when he should be learning to walk. In some cases eighteen months should be occupied in this way. The common belief that such a patient requires exercise, especially of the affected limbs, will give rise to criticism and objections. A simple argument will not prevail in the family circle, and the physician's word will hardly prevent the little patient from having many a romp. And when the case ends there will be differences of opinion. If some lameness results, it may be said that the patient should have had more exercise; and if there is no disability at all, after the strict observance of recumbency, it may be said that there had been very little the matter with the child.

The argument is as follows. It will be recalled that the ill-effects of joint disease are seen more commonly in the lower extremities than the upper, because tuberculous action is subject to resolution in the epiphyses of the shoulder, elbow and wrist, but often goes on to destruction of the articulating surfaces of the hip, knee, and ankle. And when it is noted that the arms are free, while the legs bear the weight of the body, it is reasonably inferred that the joints of the lower extremities when affected, or even suspected, should be protected by either recumbency or appropriate apparatus. The conclusion is a plain proposition, and needs no discussion or verification. It shares the simplicity of Jenner's argument when he traced the relation of cause and effect and prescribed vaccination. In another field Finlay, walking with his eyes open, apprehended the relation of cause and effect and prescribed the sequestration of the mosquito.

The necessity of reforming the environment of the lower extremities having been derived from clinical observations of joint disease, can practical conclusions be drawn in a similar manner from observing the course of infantile paralysis? Disability from this disease is seen eight times as often in the lower as in the upper extremities, and yet in the early stage the paralysis is found in all parts of the motor nervous system. The muscles of the recumbent patient are in very moderate use and in a position entirely favourable to spontaneous recession of the paralysis. The arms and hands retain this advantage when the patient is erect, but impaired muscles in the legs and feet give way at once when they meet the resistance of the weight of the body. They rapidly become elongated and attenuated, and could not well be placed in an attitude more destructive of the possibility of restoration.

When prescribed recumbency shall give to all parts the same environment, recession of paralysis will be equally encouraged in the lower and upper limbs, the disproportion of 8 to 1 will disappear, and the sum of deformity from this disease will be materially reduced.

The value of the method is thus *proved*, but it is not readily *demonstrated.* When comparing methods it is not easy to show that one is better than another. It may always be said that a case cited on behalf of a certain method may have been one that would have done well under any treatment. Tables of carefully recorded cases might lead to correct estimates, but studies of this kind are difficult and have not escaped criticism. Dr. Gaillard Thomas said, with wit and wisdom, that if there is anything more misleading than facts it is figures. Medicine and surgery are still outside of the realm of exact science. Therefore we welcome every logical and reasonable resource of prevention and treatment.

Passive motion, resistance exercises, electricity, massage, local applications, and judicious medication should be continued. They cannot interfere with the treatment proposed, and their observance may make it easier persistently to maintain recumbency—the most important agent of all.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

CYSTOTOMY. — EPITHELIOMA OF BLADDER, WITH MASSIVE CLOTS.—MR. ARTHUR EDMUNDS operated on a man, æt. 68, who was admitted suffering from intense pain in the hypogastrium and along the penis. These symptoms had only been present for a couple of days, previous to which the patient had been in complete comfort. On examination he was seen to be enfeebled and emaciated, and obviously in intense discomfort, with occasional paroxysms of severe pains. He was able to pass his water, but only in small quantities at very frequent intervals, the water itself containing a considerable quantity of blood. Per rectum, the prostate could be felt very slightly enlarged. A full-sized catheter could be passed with the greatest ease, but very little urine came away, although percussion above the pubes indicated that the bladder was a good hand's-breadth above the symphysis. A few drops of fluid were obtained, which resembled the contents of an old hæmatoma, being almost treacley in consistency and consisting mainly of blood. It was obvious that the case presented different characteristics from those of a simple retention of urine. While it is possible in some cases, Mr. Edmunds said, to pass a catheter into the bladder without relieving the patient's symptoms, it is usually because the eye of the catheter has not entered the actual cavity of the bladder, but in this case a large curved prostatic catheter was used, and also a soft rubber catheter, the latter being passed almost to its whole length, and in neither case was there any resistance. Under the impression that the catheter might be blocked, a stylet was passed down, and a clot removed from the lumen of the catheter, which was a complete cast of its interior. Even after repeated attempts, and repeatedly clearing the catheter, the patient could not be relieved, and a diagnosis of a bladder distended with blood clot was made. In cases where the bladder is thus distended, Mr. Edmunds said there are, of course, two methods of procedure. In the first the urethra is dilated, and an attempt made to remove the clots by means of Bigelow's evacuator. The other method, which was adopted in this case, was a suprapubic cystotomy, a method which is to be preferred when the source of the bleeding is unknown, as it enables the surgeon not only to remove the clot but also to deal with the bleeding-point. In opening the bladder the anterior wall was found to be excessively thin, and only a few drops of fluid escaped. On passing the finger into the bladder it at once met with a large solid mass the size of a fœtal head attenæ, completely filling up the viscus. This at first appeared to be a solid growth, but more careful inspection showed that it was a very old blood clot, covered with a certain amount of phosphatic deposit, and intimately adherent to the bladder wall at one point in the neighbourhood of the opening of the left ureter. The mass was accordingly broken up and removed. At the point of its attachment to the bladder, it was very firmly adherent, and upon separating it the base of an epitheliomatous ulcer was disclosed. The bladder was then closed, excepting at the point of insertion of a drainage tube. There were two points of interest, Mr. Edmunds pointed out, in this case:—(1) The method of causation of this enormous polypoid clot. The clot itself on section was very firm, almost as firm, indeed, as the clot which is found in the cavity of an aneurysm, but there was no lamination. A large area of it was decolourised, and it was obvious that it represented the fibrin deposited from a number of successive hæmorrhages, the hæmoglobin being washed out from the network of fibrin by the urine. (2) The question of the procedure to be adopted when an epithelioma of the bladder is discovered after a cystotomy. The bladder is perhaps, he said, one of the most hopeless situations for malignant disease, and although many efforts have been made to eradicate disease in this situation, the results have by no means been encouraging. In the present case excision was obviously out of the question, as the patient's condition was far too bad to allow of any further operative interference, and it was doubtful if it will be ever advisable to attempt such a procedure.

The drainage tube has been left in position for a week, and it is proposed to maintain it as a permanent suprapubic drainage. The man stood the operation well, and has experienced complete relief.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

NEUROLOGICAL SECTION.

MEETING HELD THURSDAY, OCTOBER 31ST.

The President, Dr. C. E. BEEVOR, in the Chair.

Dr. BEEVOR showed a case of

MYOTONIA CONGENITA.

Female, æt. 20 months. General wasting and marked flabbiness of muscles, especially of legs. Passive movements could be carried out through an excessive range. Active movements could all be feebly performed. Trunk muscles stronger, the child could sit up well. No deep reflexes obtained. To electrical currents the muscles were less excitable than normal, but there was no polar change. This was the second case of Oppenheim's disease recognised in this country. Dr. Beevor gave a short account of the condition.

Dr. JAS. COLLIER referred to two cases he had seen. Dr. S. A. K. Wilson mentioned Baudouin's recent findings in an autopsied case; the anterior horn cells and nerve roots were diminished in size, but not in number. Dr. Gordon Holmes considered that these changes did not point to neural degeneration, but might be secondary to disease of muscle. Drs. Campbell Thomson and Wilfred Harris also discussed the case.

Dr. BEEVOR also showed a case of

TOXIC AFFECTION OF MUSCLES AND LOWER NEURONES.

Male, æt. 64, shoemaker. History of illness.—February, 1907, gradual loss of power in hands and feet, beginning in left hand, then right hand, left leg and right leg in the course of two months. On admission in July, 1907, patient was helpless and unable to turn in bed. Slight nystagmoid jerkings on extreme deviation, weakness of both sterno-mastoids. Trapezii, spinati, teres, acted well. Latissimus dorsi, deltoid, biceps, supinator, triceps, flexors and extensors of wrist all profoundly paralysed, the extensors more than the flexors. Fingers could be flexed slightly, but not extended. Flexion and extension of thumb absent; abduction, adduction and opposition just possible. Intercostals strong, diaphragm weak, abdominal recti and erectores spinæ strong. Flexors of hip weak, extensors strong. Flexors and extensors of knee fairly good. Ankle and toe movements very poor. All muscles show rippling fibrillation starting at one end, usually the upper, and spreading to the other. All forms of sensation perfect. All deep and superficial reflexes absent. Electrical reactions.—Upper limb, very marked diminution or absence of reaction to faradism in all muscles; with galvanism a strong current is required, and R.D. is present in most of the muscles. Pathological report on excised portion of muscle by Dr. Gordon Holmes: (1)

Vitreous degeneration of fibres in various stages, hyperplasia of sarcoplasm and nuclear proliferation; (2) simple atrophy of small numbers of fibres; (3) no affection of the intra-muscular nerve fibres. Progress.—Steady improvement from the beginning of treatment by massage and faradism.

Dr. S. A. K. Wilson described a similar case he had seen at Queen's Square. Dr. Gordon Holmes said that the vitreous change in the muscle was indicative of toxic degeneration of the muscle, and was never secondary to nerve disease.

Dr. Wilfred Harris showed a case of

SLOWLY PROGRESSIVE HEMIPLEGIA.

A woman, æt. 35, in September, 1905, had some pain in muscles of the left upper arm, and noticed that the hand became very blue and cold. In January, 1906, she began to lose the use of the index and middle fingers. When first seen on January 23rd, 1906, the hands were intensely cyanosed, and there was marked weakness of the movements of the whole of the left upper limb, especially of the fingers. There was no muscular wasting, but extreme spasticity of the wrist and fingers, with increased deep reflexes of the fingers, wrist, and elbow. Knee-jerks were equal and brisk. Pulses very feeble on both sides. There was no weakness of the legs or any abnormality, except that she complained of the left foot feeling colder. Sphincters normal. No headaches, optic neuritis, sickness, or any other intracranial symptom. Since January, 1906, the symptoms have slowly progressed, until in February, 1907, the left hand had lost all power of movement, with only slight movement of the elbow. In February, 1907, the first trace of involvement of the left leg appeared, transient weakness and dragging, with left knee-jerk +, but flexor plantar. In May, 1907, she dragged the left leg, and the left plantar was absent. Now, in October, 1907, there was permanent dragging of the left leg, and the left plantar was now extensor. There was never any trace of anæsthesia on the hand or foot, or any sign of intracranial lesion. The spine, neck, and thorax appear normal.

Dr. Parkes Weber had published a similar case Dr. Weber and Dr. Beevor thought the condition was one of progressive cerebral sclerosis.

Mr. Percy Sargent showed a case of

NERVE-ROOT GRAFTING.

Male, æt. 19. Shown by Dr. F. E. Batten, before the Neurological Society, in July, 1906, as a case of brachial plexus palsy, following influenza two months previously. Two weeks after the illness pain in right shoulder and arm. Power in right arm suddenly lost at this time. When admitted to hospital in June, 1906, there were weakness and wasting of deltoid, spinati, triceps, and biceps. An area of anæsthesia and analgesia over shoulder and outer side of upper arm. The fifth cervical root exposed and tested with faradic current. The root was split longitudinally into an upper part which alone gave feeble contractions of deltoid and spinati; and a lower, which gave contractions of biceps and supinator longus. The upper portion was divided and its peripheral end turned down and implanted into the sixth root. Three weeks later some affection, both sensory and motor, of the sixth root area, which passed off in two or three months. Now, fourteen months after operation, deltoid and spinati were much increased in bulk, and can be used voluntarily with considerable degree of power. Deltoid and spinati reacted to faradism.

Dr. Henry Head pointed out that the recovery was probably due to nature and not to the operation. The muscles were already improving when the operation was performed. Dr. Wilson, who had watched the case, said that the triceps and serratus magnus had equally improved in spite of no operative measures. Dr. Wilfred Harris related a similar case that had improved after operation.

Dr. Ernest Jones showed a case of

ISOLATED PARESIS OF RIGHT SERRATUS MAGNUS.

Male, æt. 4. Family history.—Negative. Previous history.—Mother discovered two years ago that right shoulder blade was prominent. No previous illness or accident. Present state.—Healthy boy, with no signs of diease except as follows: right scapula elevated, not tilted. Vertebral border and angle prominent at rest, but greatly more so on flexing shoulder joint. Protrusion of right upper limb weak; elevation above head fair. Serratus magnus not palpable.

Dr. C. E. Beevor said that the weakness of the serratus was incomplete, as elevation of the limb was possible. He considered that the condition was a congenital one.

Mr. Kilgour showed a case of

MUSCULAR ATROPHY WITH DELAYED THERMAL SENSATION.

Æt. 20. In February, 1906, first noticed slight wasting of hands. This had increased since. Previous to this had frequently blistered fingers while smoking cigarettes. Although no pain was felt at the actual moment of injury, a few seconds later a sensation, similar to that caused by a burn on any other part of body, was experienced. Present condition.—The hand muscles are atrophied, and react sluggishly to faradism. Skin of fingers glossy. No anæsthesia or analgesia. Over arms and upper part of chest heat and cold are frequently confused. There is delay of a few seconds before thermal stimulus is appreciated. This is best marked on hands. There is blunting to the faradic current over the dorsal and palmar surfaces of both hands, and along inner sides of forearms and upper arms. Over the ulnar sides of hands this amounts to anæsthesia. Scoliosis present.

Mr. Kilgour considered the case one of syringomyelia.

Dr. S. A. K. Wilson showed a case of

SEGMENTAL PAN-HYPERTROPHY.

Female, æt. 26. This congenital hypertrophy of certain parts of the body was as follows. At present the left arm was much larger than the right; the left thorax was rather larger than the right, and so was the left breast: the left leg was slightly larger than the right. The right foot and leg could not be considered normal, and the first two fingers of the right hand were larger in proportion than the others of that hand. The hypertrophy was a true one, affecting bones and soft tissues alike, and Dr. Wilson proposed the term "segmental pan-hypertrophy" for the condition. The telangiectatic and pigmented areas of the skin occurred generally.

Dr. Parkes Weber had collected the published cases of this condition recently, and recorded some of his own.

Dr. Farquhar Buzzard showed a case of

HUNTINGTON'S CHOREA.

Male, æt. 49. Healthy until two years ago, when he had a "nervous breakdown" lasting about two months, during which he had difficulty in speaking. Six months ago first noticed involuntary movements of the legs and trunk, associated with some pain in left leg and abdomen. Movements had continued with varying intensity. Latterly he has become stupid, memory failing and some depression. Present condition.—Choreic movements, affecting chiefly the trunk and large limb muscles. Some mental deterioration.

Dr. Buzzard also showed a case of

DISEASE OF THE CERVICAL VERTEBRÆ; WITH PRESSURE SYMPTOMS.

Girl, æt. 15. January, 1906. The neck gradually became stiff, and she noticed a small swelling about the size of a walnut, which was rather tender. In the course of two months she became unable to move her head at all, except slightly to flex it, and by June, 1906, the swelling had increased to its present size. At the end of 1906 came a gradual return of movement in the neck, and she has been able to move it more or less freely ever since. In March, 1907, the right arm began to feel numb and gradually weakened, and a week or two later the right leg began to drag.

For three months these limbs were more or less completely paralysed. In June there was retention of urine for three weeks. There was a large rounded, hard, painless swelling occupying the back of the neck below the level of the hairy scalp. This part of the neck was rigid, but the movements of the head were remarkably free. Strings of firm, discrete, slightly-swollen glands might be felt in the cervical triangles. The right arm was immobile at shoulder and elbow; the hand was of the *main-en-griffe* type. The left arm was rather weak, and there was slight wasting of the small muscles of the hand on this side. Both legs were weak, especially the right. There was a diminution of the sensation of pain in both legs, more on the right side, and in both arms, more on the right side. The deep reflexes were everywhere brisk, with double knee clonus, and a double extensor response.

Dr. **Henry Head**, Dr. **Wilson**, Dr. **Grainger Stewart**, and Mr. **Donald Armour** discussed the results of operative treatment of Pott's disease.

Dr. **James Taylor** showed a case of the Landouzy-Dejerin type of myopathy. The patient, a woman of 28, had first suffered from facial weakness, about eight years previously.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held October 18th, 1907.

Mr. R. Clement Lucas, F.R.C.S., in the Chair.

A paper on the SIMULATION OF SOME OF THE SYMPTOMS OF PRIMARY AMAUROTIC IDIOCY

by a tumour of the interpeduncular space, by Dr. E. C. Williams, of Bristol, was read. The patient was a girl, æt. 15 months. For three months she had been gradually failing to take notice of objects, and had been getting weaker. On admission she lay quite still and motionless, was somnolent, and not disturbed by any sounds, even though quite close to her ears. Her eyes were firmly closed, and when sat up in bed her head rolled either backwards or to one side. The arms were slighty spastic, the wrist-joint was flexed, and there were slight athetoid movements of the fingers. The legs were spastic, and remained extended when the patient was raised from the bed. The knee-jerks and plantar reflexes were exaggerated on admission, but towards the end the spasticity decreased and nearly disappeared. Babinski's sign was present; sensation was diminished. The pupils were dilated and fixed; the right was divergent. There were no fundal changes, the disc and macula both being normal. The child died 19 days after admission from œdema of the lungs and heart failure. *Post-mortem.*—A cauliflower growth the size of a walnut was found springing from the pituitary body; microscopical examination showed it to be a round-celled sarcoma. There was also a small similar growth in the parietal region. The case resembled primary amaurotic idiocy in the paralysis of the greater part of the body and the muscles of the neck, in the diminution of vision, leading to absolute blindness, and in the marasmus and fatal termination. It differed in that it did not present the characteristic fundal changes, and in its more rapid progress.

A case of *Associated Movements of the Upper Eyelid and Jaw* was shown by Mr. **Sydney Stephenson.** There was slight ptosis on the left side, and when the child moved the jaw the lid of the unaffected eye showed rhythmical movements upwards and downwards. An unusual feature in his case was that the movements affected the eye which had no ptosis. The explanation commonly received, assumed that the levator palpebræ superioris was not supplied entirely from the third nucleus, but also by fibres from the fifth nerve nucleus, so that when certain of the muscles of mastication were thrown into action, the upper eyelid participated in the movements of the jaw.

Mr. **Stephenson** also showed a case of *Tuberculosis of the Iris and Ciliary Body,* with reference to Calmette's ophthalmo-reaction. The eye had been inflamed for six months. The anterior chamber of the left eye was more or less filled with solid-looking yellowish-grey exudation, so that only a faint indication of the position of the pupil could be obtained. The eye was reddened, flushed easily, and dreaded the light somewhat.

A case of *Congenital Ptosis Treated by Motais's Operation of Tendon Transplantation,* very slightly modified, was also shown by Mr. **Stephenson.** The patient was a girl, æt. 2 years and 10 months. None of her nine brothers and sisters had any deformity. Family history unimportant. The left eye was the subject of incomplete ptosis, the pupil being practically covered by the drooping upper eyelid. There was no epicanthus, and no associated deformities. Upward movements of the eyeball were good, and no synkinetic movements were noted. The superior rectus was divided into two parts; the outer was stitched into the upper eyelid, and the knot tied on the skin surface of the latter. Seven days later the stitches were removed.

A case of *Lupus Vulgaris of the Face,* due to inoculation by a finger-nail, was shown by Mr. **George Pernet.** It was the result of an accidental scratch by another child.

The **Chairman** alluded to three cases which had been under his care. One man scraped his knuckle by striking a man in the mouth; another man was bitten on the forefinger; and the third case followed circumcision.

A case of *Multiple Lupus Vulgaris* following an attack of measles was also shown by Mr. **Pernet.** It had previously been brought before the Society by Dr. Poynton for lichen scrofulosorum.

The **Chairman** remarked that in many cases the disease was spread in the same person by scratching.

A case of *Generalised Alopecia* in a Mongolian idiot was brought forward by Mr. **Pernet** to demonstrate the good growth of hair on the scalp, as the result of persevering local treatment, and the exhibition of thyroid extract.

An unusual case of *Infantile Paralysis* was shown by Mr. **Lockhart Mummery.** The child, æt. 18 months, lost the use of all its limbs during an illness 12 months previously, though the arms were only slightly affected. Since then the child had recovered the use of the arms, but the flexor action of the fingers of the right hand was not quite normal. There was very slight extensor power in the right thigh, but none in the left limb. The adductors on both sides were completely paralysed.

A case of *Genu Recurvatum* was also shown by Mr. **Mummery.** The child, æt. 3 months, was born with legs bending the wrong way. Both legs were hyperextended to an angle of 30 degrees, and could not be flexed beyond a straight line.

A case of *Synostosis of the Upper Ends of the Radius and Ulna* was shown by Mr. **Hugh Lett.** Both arms were involved, and skiagrams showed that the radius and ulna were united by bone for about an inch at their upper ends. The right radius was much curved. The right arm was in a position of nearly complete pronation, the left arm midway between pronation and supination. Flexion and extension of the elbow joints were perfect.

The **Chairman** said that congenital ankylosis was very rare; some explanation such as intra-uterine fracture, or an arthritis very early in life, seemed necessary to account for the condition.

A case of *Osteogenesis Imperfecta* was shown by Dr. **Langmead.** The child was born after an easy labour seven weeks previously, and was brought to the hospital on account of the deformities four days later. The legs and thighs were sharply bent, the arms and forearms were also bent, but not so much. Amniotic dimples were seen on both legs, and on the right thigh. The post-anal dimple was well defined. Skiagrams showed fractures of the right humerus radius and ulna, of both tibiæ and fibulæ, and of each femur in two places, making eleven in all. There was marked callus formation about some of the fractures, especially those of the leg and thigh bones. The shadow given by the bones was no less dense than normal. There were nine other children in the family, all well, and there was no evidence or history of syphilis in the parents.

Mr. **Hugh Lett** alluded to a similar case he had brought before the Society last session, and asked whether there was any suggestion of heredity or sign of hydrocephalus in Dr. Langmead's case.

Dr. **Langmead** replied that there was no hydrocephalus or history of heredity.

A case of *Congenital Heart Disease* in a boy, æt. 5 years, was shown by Dr. C. W. **Chapman**. The only symptom he had had was some shortness of breath on exertion. He had had no illness beyond an occasional bronchial attack, one being so severe as to require confinement to the room for six months. He was exceptionally well developed, and his mental condition was beyond the average. The cardiac dulness was not increased. In the pulmonary area there was a harsh systolic murmur which was conducted upwards and outwards. Over the midsternum there was a loud, blowing systolic murmur which could be traced in all directions, and was faintly audible in the midscapular region. The aortic sounds were normal. There was no cyanosis, and the finger-tips were not clubbed. Dr. Chapman considered that the interventricular septum was patent, with stenosis of the pulmonary artery. The points of interest were the absence of usual symptoms (with the exception of shortness of breath on exertion), and the boy's excellent development.

Dr. **Carpenter** agreed with the diagnosis of congenital malformation of the heart and stenosis of the pulmonary artery. The murmur which was heard all over the front of the chest was better heard on the left than on the right, and it was also heard in the great vessels of the neck. When the murmur was so conducted, he looked upon it as a sign that the septum ventriculorum was perforate, but unfortunately it was not an infallible sign. He did not agree that there was no right-sided hypertrophy, and pointed out that an X-ray examination would determine the point. It was not uncommon for cases of congenital heart malformation to give no physical indications of their infirmity until an initial attack of bronchitis or broncho-pneumonia, from the onset of which, cyanosis and other signs often dated. Mild varieties of narrowing of the pulmonary artery, such as this appeared to be, were not incompatible with long life. The dangers lay in the balance of the circulation being upset by lung troubles, and by the onset of endocarditis further complicating matters.

Dr. **Cautley** remarked that the patient was a good illustration of the fact that in these cases the prognosis depended on the general health of the child and the circulatory effects, rather than on the loudness and distribution of the murmur.

FRANCE.

Paris, Nov. 3rd, 1907.

Acute Œdema of the Lungs.

The treatment of acute œdema of the lungs must be prompt to be successful. The best authors (Hayem, Huchard, Dieulafoy) are agreed on the necessity of blood-letting whenever practicable. From 10 to 12 ounces of blood should be drawn, the procedure to be renewed the following day if necessary. Under its influence the threatened asphyxia disappears with rapidity. If for certain reasons general blood-letting is not accepted, or possible, wet cupping or leeches should be employed, although not to the same advantage.

Spartein or strophanthus is useful to strengthen the action of the heart; digitalis should be reserved for the sub-acute or chronic form depending on cardiac origin. Champagne might be freely given, while chloride of calcium has been recommended by Sztahovszky. Ipecacuanha is useful in œdema complicated wtih general bronchitis.

Oxygen gas may be respired with benefit. M. Huchard recommends injections of camphor and oil (1—10) and strychnine is very beneficial, and should be preferred to cafein. Morphia is absolutely counterindicated and dangerous. The same may be said of blisters. As to iodide of potassium, it should be suppressed as soon as the first symptoms of œdema set in.

In rheumatism complicated with pulmonary trouble, salicylate of methyl as an external application is dangerous, as it possesses marked œdematogenic properties.

Suppression of salt in food is absolutely indicated in acute œdema, as œdema is one of the consequences of the retention of chlorides.

Treatment of Hæmophilia.

At the recent meeting of the Congrès de Médecine, M. Carrière (Lille) read a paper on the treatment of hæmophilia. The patient should, if possible, be ordered a change of climate, either to the seaside or to the mountains, to renovate the blood. A tonic régime should be instituted (eggs, meat, vegetables), iron or arsenic is useful against anæmia, but has no direct action on the hæmophilia itself. For this, chloride of calcium, gelatine, serotherapy, constitute the most favourable treatment. Chloride of calcium might be given in 15gr. doses four times a day (adult), and continued for some time. Gelatine is less satisfactory. Serotherapy was recommended recently by Weill. An ounce of the serum of the horse might be injected every 10 or 15 days.

When an operation seems necessary on a patient suspected of hæmophilia (vegetations, amygdalotomy, avulsion of a tooth), the coagulation of the blood should be examined before operating, and the patient submitted to a preparatory treatment several days before the operation. Injection of an ounce of animal serum every day; enemas of half-an-ounce of gelatine three times a day; administration of a mixture, containing from one to two drachms of chloride of calcium.

In case of hæmorrhage, the usual local methods of arresting it, according to the region, should be employed; plugging for epistaxis, obliteration of the dental cavity with wax, after avulsion, etc.

The Continental Anglo-American Medical Society.

The annual meeting of this Society was held recently in Paris. Dr. Coldstream (of Florence) was in the chair, and the following members were present: Mr. G. H. Brandt and Dr. Egerton Brandt (Nice and Royat), Dr. Cormack (Vichy and Hyères), Dr. Cafferata (Spa), Dr. Douty (Cannes), Dr. Heinemann (Bad Nauheim), Dr. Johnston Lavis (Beaulieu), Dr. Trèvès-Barber (Geneva), Dr. Sillery Vale (Arcachon), Dr. Bull, Dr. Maguin, Dr. Gros, Dr. Jarvis, Dr. Rivière, Dr. Marucheau, Dr. Turner, Dr. Warden, and Dr. Leonard Robinson (Paris), hon. secretary.

After the presentation of the annual report it was announced that a brass tablet to the memory of the late Dr. Alan Herbert, Officier of the Légion d'honneur, had been erected to his memory by members of the Society in the chapel of the Hertford British Hospital, Paris.

On examination of the voting papers to fill the vacancies on the Executive Committee, it was found that Dr. G. Sandison Brock (Rome), Dr. Maguin, and Dr. Warden (Paris), and Dr. A. Hugh Gibbon (Naples) had been elected. The following five candidates for membership were duly elected: Frederik Michael Bishop, M.R.C.S., L.R.C.P. (Varenna 3, Cadenabbia); Marc de Levis, M.D.Lyons (Nice); Bryden Glendining, M.B., B.Ch.Durham (Madrid); Frederick Aylmer Hort, M.R.C.S., L.R.C.P., M.D. Montpellier (Nice and Aix-les-Bains); Arthur Gerald Welsford, M.D., B.C.Cantab, F.R.C.S.Eng., D.P.H. Cantab (Rome). There were no fewer than eight motions down on the business paper, but these were mostly withdrawn after full discussion. It was, however, generally considered that it would be an advantage to members of the Society and to the travelling public, if a list could be made as complete as possible by the inclusion in it of all duly qualified and eligible British and American practitioners on the Continent of Europe and North Africa. It was also decided "that no members shall be eligible to hold any office in the Society unless the full amount of his annual dues be paid." The motion that "five black balls shall be considered sufficient to exclude a candidate," gave rise to considerable discussion, but it was ultimately carried.

Dr. Heinemann said that as a result of the discussions on the various motions he proposed that the Society appoint an ethical committee; the proposal was seconded by Dr. Maguin, and will be discussed at the next annual meeting. A hearty vote of thanks to the Chairman brought the meeting to a close. In the evening the annual dinner of the Society was held at the Hotel du Palais D'Orsay, when twenty members of the Society were present, besides many guests, the gathering proving a most enjoyable function.

RONTGEN RAYS IN MALIGNANT TUMOURS.

The influence of X-rays in malignant tumours was set forth by Dr. Béclèse at the recent surgical congress. It is well-known that the neoplastic cells are more sensitive to the action of the rays than healthy cells; the former are destroyed while the latter resist. This properly explains the curative action of the rays which succeed very well in certain maladies, producing a complete cure; at other times the improvement is only temporary, and in many cases the effect is absolutely nil.

Complete cures are observed in cutaneous epithelioma provided it does not penetrate further than the skin.

Complete disappearance is also observed in certain tumours of the breast. The slow development of a neoplasm of the breast, when it is movable under the skin and well in front, has a chance of being cured by radiography. Even when the tumour is ulcerated superficially, and to more or less extent, success may be hoped for. Tumours of the breast that have returned after operation, under the form of indurated ganglions, limited to the cicatrices of the operation or in its immediate neighbourhood, easily disappear.

However, when the relapse attacks the deep tissues, the rays are without effect.

In epithelioma of the mucous membrane, the results are not satisfactory. Exception might be made, however, for epithelioma of the mucous membrane in continuity with skin and in the neighbourhood of the natural orifices; lips, arms, external genital organs, prepuce flaws, labii; neoplastic ulcerations of the lips have frequently disappeared as well as the submaxillary glands which accompanied it. A few isolated cases of cancer of the tongue have been cured, at least for a time, consequently radiotherapy should be tried, at least at the beginning when the surgeon hesitates to pronounce the word "operation." Later it will be simply a complement of the operation to destroy the visible or invisible germs which escaped the action of the knife.

In the treatment of sarcoma, for which the bistomy is given the first place, the rays complete the operation and prevent relapses more successfully than in other forms of cancer.

During the discussion which followed the statistics of 107 cases were examined: Cutaneous epithelioma furnished 23 cures out of 28 cases (82 per cent.); epithelioma of the mucous membrane, one temporary improvement out of 17 cases, in other words, completely unsuccessful; tumours of the breast: two small fibroma cured, 11 characterised cases of cancer, uninfluenced; 2 successful cases out of 7 relapsing cancers. Some sarcomata and osteo-sarcomata (five cases) notably improved.

To resume, the X-rays cure almost with certainty cutaneous epithelioma, improve sarcoma, and certain tumours of the breast, especially recent relapsing cancers, and fail completely in all other neoplasms. Nevertheless, the treatment, exercising a moral action, at least, can be employed with precaution in those cases where surgery has declared itself powerless.

GERMANY.

Berlin, Nov. 3rd, 1907.

IS OPIUM USEFUL OR HARMFUL IN ACUTE PERITONITIS?

THIS is an exceedingly important question discussed by Prof. Pel, of Amsterdam, in the *Berliner klin. Wochenschr.* (32/07).

He says that during the last few years many practitioners, especially those inclined to surgery, have objected to the employment of opium in acute perityphlitis, and have rejected it as unsuitable. And now matters have advanced so far that even physicians—Dieulafoy, of Paris, for example, Bourget, of Lausanne, Albu, of Berlin, and others—have ranged themselves as opponents of opium.

Although thoroughly convinced of the high importance of theoretical considerations and experiment, he takes his stand on this: that questions such as the above can only be solved by clinical observation at the bedside and experience. From observation of 30 cases the writer is convinced that opium should not be rejected in treatment of acute perityphlitis. He considers the useful influence of opium in this disease as one of the best founded facts in medicine. The injurious effects of vomiting on the heart and abdominal cavity are partly eliminated by it; the restfulness in bed, so urgently needed, is aided; rest at night is assured, and the tormenting feeling of thirst is diminished. The spasmodic peristaltic contractions which tear away adhesions and further the extension of the mischief are quietened, and the limitation or encapsulisation of the inflammatory process is assisted. Thus the healing art assists nature in its endeavours to limit the spread of the disease, and at the same time the humane aims of medicine are brought into play, and the three requirements of our wise forefathers of an ideal method of treatment—*tuto, cito, et jucunde*—receive their fulfilment.

The author gives the opium in the form of laudanum or tinct. opii, in doses of 10 or 15 drops every hour or every two hours, diminished as soon as the patient's condition will allow. With suitable applications of ice, small doses of opium will often answer the purpose. If the pain has to be mastered quickly, it will be proper to begin with a subcutaneous injection of morphia. Small rectal injections of a few drops of laudanum also act favourably. Moreover, the patients bear opium even in large doses remarkably well. Any possible constipation accompanying the opium is not a contra-indication. The writer has never seen any trace of intestinal paresis, meteorism, or abnormal decomposition of abdominal contents or absorption of intestinal poisons in consequence of the opium treatment. Neither can he agree with Albu's assertion that opium often leaves a tendency to constipation behind it. Not infrequently one gets the impression that, as in lead colic, opium has the effect of furthering intestinal evacuation by its anti-spasmodic powers. He is quite convinced that purgative treatment is the worst of all, that here it may be said, "*Qui purgat, male curat.*"

A second objection brought mainly by the surgeon against the use of opium in acute perityphlitis is that it "masks" symptoms. The author does not share even this view. The bowel is not paralysed (as believed by Albu) by the opium, but the undesired, irregular, and painful contractions are relieved by suitable—*i.e.*, therapeutic, non-poisonous doses of the drug. The subjective feeling of well-being is increased, the patient rests better, the vomiting becomes less tormenting, and, of course, the abdominal pain becomes less severe. He cannot understand how a "good" observer can be deceived if he watches all the symptoms of the disease (pulse, tongue, temperature, respirations, general condition, blood, urine, abdomen, etc). Such deception could only occur to one who was not a good clinical observer, or one who treats his patients with really poisonous doses of opium.

Naturally, absolute rest in bed, ice applications, and the strictest dieting are necessary. In the most acute cases in which the diagnosis is assured and the other conditions are favourable, the so-called early operation is rational and should be recommended during the first 24 or 36 hours. This method of treatment can scarcely be carried out in one-third or one-fourth of the cases. As soon as the general and local symptoms point to suppuration, the abscess should be opened, but this will only be in a comparatively small number of cases.

The writer thinks it a great pity that the general practitioner who has the great advantage of meeting all classes of cases, mild and severe, and in all stages from the earliest to the fully developed, should have taken so little part in the solution of this important problem, as they are in the best position to give a reliable opinion on the immediate and subsequent results of any method of treatment.

The author would lay down two propositions scarcely in accordance with the spirit of modern medicine, but in agreement with the words, *Vidi quid scripsi:*—

(1) With proper treatment, acute perityphlitis (appendicitis, periappendicitis) will run a favourable course in 90 per cent of the cases.

(2) The physician who treats his cases of perityphlitis on these principles by no means neglects them. The disadvantages of giving opium, and the advantages of a laxative line of treatment, are theoretical rather than based on accurate clinical observation. That physician who withholds opium in suitable doses from his cases of acute perityphlitis (exceptis excipiendis) is guilty of the sin of omission; he who treats them with laxatives, of malpraxis.

Amongst the numerous subjects discussed at the International Congress for Hygiene and Demography held in Berlin was that of the

ÆTIOLOGY OF TUBERCULOSIS.

Prof. Arloing, of Lyons, believed there was only one bacillus of the disease. The supposed different kinds or types were temporary varieties whose special forms lasted only as long as the circumstances that gave rise to them.

Strictly defined types were rarely found. The bacilli comprised an almost unlimited series of individuals whose forms gradually passed into each other. This changeableness sufficed to explain the usual distinguishing signs of tuberculosis in mammals and birds. Both from a medical and hygienic standpoint there was a real danger in laying down principles for the prevention of tuberculosis on such slight differences.

Dr. Ravenel, Philadelphia, said the digestive tract was frequently the point of entry of the bacillus. The bacillus could penetrate the uninjured mucous membrane of the intestines without causing any wound. This occurred mostly during the digestion of fatty foods. The bacilli passed with the chyle along the lymph tracts, and through the thoracic duct into the blood, which carried it into the lungs, where by the filtrating action of the lung tissue they were to a great extent retained. Infection through the digestive tract was particularly frequent in children. The milk of tuberculous cows was the cause in many cases.

The disease could be conveyed by touch, by kissing, unclean hands in cleaning up after cases of death, by the washing of vessels that had been used by tuberculous patients, etc. These kinds of infection, however, played only a subordinate rôle in the spread of the disease.

Hr. Flügge, Breslau, was of opinion that the disease was spread mostly by inhalation of tuberculous dust.

Prof. Ribbert, Bonn, concluded from the examination of cadavers that the disease was localized most frequently in the bronchial glands and in the lungs. In the majority of cases that in the glands was the only gland tuberculosis in the body. It could be of only aërogenous origin. Intestinal infection was of far less importance.

Prof. v. Schroetter, Vienna, said the lungs were most frequently the first affected.

Hr. Dieterlen said that if bacteria were injected into animals by the rectum they were found in the lungs four hours later. The germs ascended the intestinal tract, and passed into the lungs through the œsophagus. When the œsophagus was ligatured, they were never found in the lungs.

AUSTRIA.

Vienna, Nov. 3rd, 1907.

TUBERCULOSIS.

SCHRÖTTER had a paper on the necessity of notification in tuberculosis. This subject had been fully discussed at the International Conference, and a resolution passed (*a*) that all recognised cases of tuberculosis, (*b*) all dying of the malady, (*c*) and all removals of the disease should be carefully notified. He said (*a*) had been objected to on the ground of its scope; it is too extensive, and includes many cases not at all dangerous to the public, while (*b*) and (*c*) were accepted by both the International Congress and the Hague Committee. Now, if all cases be not notifiable, at what stage must we notify—those who are dangerous or those who are likely to become dangerous. We have often cases coming before us of such a light character that no notice is taken of them till they burst into a conflagration. We have often cases of local condition of the nose that end fatally in meningitis. These are cases equally as dangerous as if pleurites pneumothorax or other lung trouble had occurred. The social position is certainly one to be considered, where every care and cleanliness would be exercised.

All that authorities have to go on hitherto are the statistics of the dead, which must be accepted with some reserve, as many bronchitic, pleuritic, etc., cases may come under this category. This is now changed. There is no excuse for a false diagnosis with Pirquet's cutaneous or Calmette's ophthalmic test, which can be made in a few hours without any danger of injury to the patient.

It is not for us to point out the utilitarian side of the question to authorities, but it must be left in their hands, with the possibility of determining every case of this character within their area.

It is evident from our present knowledge of the disease that notification must come in its most comprehensive form, and that the more advanced cases must be isolated in sanatoria, or provided with hospital accommodation. When we examine the objections to notification we must admit they are weak and against the interest of the patient, but it must also be admitted that if such knowledge were made public it would injure many of the more healthy and less dangerous in their social and industrial life. It must not be forgotten that this information is confidential, and not for the public, although it is for the public good. If the subject affected be not dangerous, no particular notice would be taken, although the knowledge would be useful in important offices. It is interesting in this direction to read the accounts of Philip, Calmette, and Kayserling, of Norway, who have educated the authorities to take every care against the spread of this malignant disease. Here general notification is observed, and what is possible in this country can surely be carried out by other cultivated nations. It is important, however, that every effort should be made by the authorities for the proper treatment of every one so notified, and that reasonable regulations should be laid down for their observance. Raw, of Liverpool, advocated notification for the so-called severe cases which would be dangerous to the community. Milder or latent cases should not be pressed for notification. Obligatory notification existed in Sheffield on these lines, and appear to work satisfactorily. Glasenapp, Berlin, proposed an amendment that all cases dying from lung or throat tuberculosis should be notified, and the dwellings disinfected, and added that these diseases in life should be carefully observed. Teleky thought that obligatory notification of all cases of tuberculosis was impracticable, and would be resisted by the people. He thought a more obligatory disinfection of dwellings where advanced tuberculosis had been located, particularly in sanatoria or watering-places where lung diseases were treated, should be thoroughly supervised. Hermann, Prague, as a jurist, welcomed the general obligatory notification as a reasonable and effectual method of checking the diease. Every individual was a member of the State, and claimed its protection from infectious diseases such as tuberculosis and syphilis.

TUBERCULOSIS.

At the recent conference Flügge supported Weichselbaum in the belief of infecting by the bowel easier than the lung. The subcutaneous injection was no more potent than the inhalation, but acted quicker, while the alimentary canal conveyed a million times more bacilli than either of the other two portals. He admitted, however, that his experiments showed that fewer bacilli were taken in by the lung, but they acted more violently and virulently than inoculation or alimentation. But we must make an allowance for morals and customs when comparing animal experiments with human results. Children may be more easily infected by cheese, butter, milk, and unclean fingers, etc., than elderly persons, but the latter cannot escape the fomites or the organism in the dry dust from sputa, etc. The "Tröpfchen" or drop theory is quite plausible and possible. A patient suffering from the disease coughing causes the finer part of coughed matter to combine with the floating dust that is directly wafted to the healthy lung where it is deposited to germinate. This may be the mode of infection where long associations are kept up, such as between mother and son or man and wife, but in communities or large assemblies it is not so likely from the rapid oxidation in the fluid state weakening the potency of the virus.

HUNGARY.

Budapest, Nov. 3rd, 1907.

ACCORDING to the educational number of a leading medical weekly, the number of medical students has been increasing steadily since 1896. The University of Budapest had then about 500 students, whereas this this year it counts about 1,000. The standards of preparation of study and of graduation have been raised considerably, showing that there is a disposition on the part of all concerned to elevate the standard of the profession by bringing into it men and women who are better prepared to practice medicine, and who will be a credit to the profession in every way.

PUBLIC LECTURE ON SMALL-POX.

From the occasion of the small-pox epidemics in Vienna, Dr. Becsey gave a lecture to the lay people on the importance of second vaccination of adults. On the same day he discussed in the Medical Society the symptomatology and differential diagnosis of small-pox, and showed lantern slides made from photographs taken of patients at the Isolation Hospital. He also quoted the statistics of the Vienna Department of Health, showing the incidents and death-rate of the disease in vaccinated and unvaccinated persons, and described the methods of vaccination. He emphasised the necessity of using virus which was efficient. Failure to obtain a take was usually due to inert virus, and sometimes to improper technic in vaccinating.

SYMPTOMS OF HEREDITARY SYPHILIS.

Dr. Selley, in a lecture held at the Royal Medical Society's recent meeting, stated that in establishing a diagnosis of hereditary syphilis there were three points known as the triad of syphilis, which had long been looked upon as of the greatest value. These were Hutchinson's teeth, interstitial keratitis, and a particular form of deafness. These points were considered in their order. He reported several cases of late hereditary syphilis gleaned from the literature, and others that had occurred in his own practice.

AGGLUTINATION OF TYPHOID SERA.

Dr. Szèkacs has made the observation that the serum of patients suffering from typhoid will also agglutinate the paratyphoid germs, and it may be difficult to say whether the patient suffers from typhoid or paratyphoid. He pointed out the necessity of always determining the highest dilution in which agglutination will still take place. It may also happen that the typhoid bacillus will not be agglutinated by typhoid serum in low dilution; while with high dilution clumping will be perfect. In a case mentioned a dilution of 1 to 80 was tested against both typhoid and paratyphoid. The latter was clumped actively, the former not at all. A diagnosis of paratyphoid, therefore, seemed probable, yet, on further testing the serum, active agglutination was obtained with typhoid at 1 to 640; while the paratyphoid was not at all agglutinated in this dilution. The microscopic test is always more delicate than the macroscopic.

ON THE VALUE OF THEOPHYLLIN.

Dr. Kollarits analysed a series of 728 cases, which had been treated with theophyllin, with the following results:—In 326 cases the drug accomplished the desired effects; in 40 cases the improvement was only relative, and in 62 no good results were seen. In 85 patients theophyllin brought about a satisfactory diuresis after most other diuretics had failed, and in 55 diuresis was much more marked with theophyllin than with the other drugs. No difference in action could be detected between the pure drug and the various salts on the market. After effects were seen in as high as 31 per cent., but in the great majority these were very slight, and chiefly gastric (vomiting, diarrhœa and nausea). Two patients died soon after taking a powder, but it is impossible to decide if the latter was really responsible, since the cardiac weakness was extreme in each case. Collapse was observed three times, and in a large number such minor disturbances as languor, insomnia, and general nervousness. The best results were seen in cardiac hydrops, and (contrary to some observers) in acute nephritis; but good can also be accomplished in chronic nephritis, cirrhosis of the liver, and in exudative pleuritis. Often the first dose is not well borne, but a tolerance is soon established. At first no more than 0.1 grains should be given.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

TRAINING OF DEFECTIVE CHILDREN.—The first special school for the training of defective children in Edinburgh was opened on October 28th by Mrs. Burgwin, Superintendent of Special Schools under the London County Council. Mr. W. H. Mill, Chairman of the School Board, remarked that in Edinburgh they had been somewhat dilatory in providing a school of this kind, and they were indebted to Mr. J. W. Gulland, M.P., for having initiated the movement among them. In the school they intended to teach both mentally and physically defective children, and they had provided ambulance wagons to bring the scholars in the morning and take them home at night. They had two teachers, one trained to instruct mentally defective, and one trained to deal with the physically defective. A nurse would also be in attendance. Mrs. Burgwin, in the course of an interesting address, explained the methods adopted, and the class of children dealt with, in such schools. Imbeciles should be excluded. They would deal with those who manifested the first deviation from the normal—the child who could not read, but could sum, who had fits of temper, who was not quite right, but in regard to whom you could not say what was wrong. These children were very often nervous, untruthful, desirous of saying anything that would please, and dirty in their habits. In her own special schools many pupils who had seemed almost hopeless were now earning good wages; it was cheaper to spend money on schools than on penitentiaries and poor houses. She was almost hopeless about such cases when they reached adult life. The proportion of defective children was about 1 per cent., boys being more numerous than girls. In London about one-third of the children could always earn after leaving school; about one-third were doubtful. She advocated in connection with the least impressionable cases the establishment of good, bright, working colonies. A vote of thanks was moved by Dr. Clouston, and seconded by Mr. Leslie Mackenzie.

CARE OF FEEBLE-MINDED CHILDREN IN GLASGOW.—The first annual meeting of the Association for the Care of Defective Children was held on October 31st, Provost Bilsland in the chair. He moved a resolution commending the work of the institution to the public to obtain funds for the extension of the present institution at Kirkintilloch. At present only girls were dealt with, and the directors were most anxious to include boys. Sir John Tuke seconded, and spoke in terms of high praise of the management of the institution. Dr. John Macpherson, H.M. Commissioner on Lunacy, proposed a resolution recognizing that the work of the Association was much hampered by lack of statutory powers to retain feeble-minded children under its care against the wish of parents. He reminded his audience that the State was proverbially slow to interfere until philanthropic effort had paved the way for it, and that the whole of the great lunacy system of Scotland had been initiated by private enterprise and charity. Excellent as the work of the defective schools was, it did not protect the children or follow them through life as it ought. Perhaps when something like ample accommodation was found all over the country for feeble-minded children people would begin to talk about an increase of imbecility as they now did about an increase of insanity. At present they had no power to keep these children after a certain age, with the result that many of them at the most critical age of their lives went back to unsuitable guardians, and lost all the moral and physical good they had gained. In seconding the resolution, Miss K. V. Bannatyne pointed out that at present they had actually more power in the case of a normal child who lived in dangerous surroundings at home than they had in the case of the feeble-minded; it was necessary that the legislature should rectify this, and give them powers of compulsory detention.

Royal Medical Society.—The inaugural address of the 171st session of this ancient Society was delivered in their hall on October 24th by Professor Sherrington, Liverpool, who took as his subject "Inhibition." The lecture was illustrated by lantern slides, and was much appreciated. In replying to a vote of thanks, Professor Sherrington spoke of the extraordinary vitality of the Society—he thought it must be unique. In London there was the old Abernethian of St. Bartholomew's, but that, though more than 100 years old, was a mere youngster beside the Royal Medical Society.

Presentation to Dr. Carswell.—On October 24th the Lord Provost publicly presented Dr. John Carswell with a cheque for £415, and a silver salver bearing the following inscription, "Presented in token of their regard for his personal qualities, and in recognition of his services to the community, as a member of the Town Council and other philanthropic and public boards, and of his eminent services to the special department of medical practice to which he has devoted his life." Appropriate speeches were made by the Lord Provost, Sir John Batty Tuke, M.P., and Dr. Oswald.

St. Andrews University Rectorial Election.—Two nominations for the Lord Rectorship had been made, namely, Mr. Andrew Carnegie and Lord Avebury, and the poll had been arranged for November 2nd. On the day preceding the polling day, however, considerable surprise was occasioned by receipt of the intimation that Mr. Carnegie had declined to allow his name to go forward. Lord Avebury has therefore been returned unopposed. It should be stated that Mr. Carnegie had been nominated without his consent having been obtained.

BELFAST.

Visit of their Excellencies the Lord Lieutenant and Lady Aberdeen.—During the past week we have had a three days' visit from the Viceregal party, who spent a busy time in visiting various institutions in the city, and attending meetings. Lady Aberdeen was specially active in her interest in health affairs, addressing the opening meeting of the Belfast Branch of the Women's Health Association, speaking at a meeting of the Ulster Branch of the Irish Nurses' Association, and opening a bazaar for the Belfast Hospital for Sick Children. At the first-named meeting the chair was taken by the Lord Mayor, the Earl of Shaftesbury, and the attendance was very large and representative. Lady Aberdeen gave a stirring address on the problems of physical deterioration, and the awakening of the national conscience in health matters. She also put in a word for the Tuberculosis Exhibition shortly to visit Belfast. A resolution approving the formation of a local branch was moved by the Dowager Marchioness of Dufferin and Ava, who since her illustrious husband's death has lived at Clandeboye and interested herself deeply in local philanthropic movements. The High Sheriff, Dr. P. R. O'Connell, J.P., was able to speak with effect from his wide experience as a hospital surgeon in Belfast of the ravages of tuberculosis among the working classes of the city; and Dr. King-Kerr, J.P., the Chairman of the Public Health Committee, also spoke with local knowledge. A long and most successful meeting was brought to a conclusion by a vote of thanks to the Lord Mayor, moved by the Lord Lieutenant, and seconded by Sir John Byers, M.D. On Thursday afternoon Lady Aberdeen addressed a meeting of the Ulster Branch of the Irish Nurses' Association, which was presided over by Lady Hermione Blackwood, herself a trained nurse. Her Excellency appealed to the nurses to help in every way in their power towards the success of the Women's National Health Association, and pointed out to them how much benefit such an Association might confer on the community by dealing with such subjects as the provision of consumptive sanatoria and the regulation of food and milk supplies. In regard to the compulsory notification of consumption, she said that there were some things in the Act which would bear hardly on patients unless great care were exercised by the local authorities who put it in force, and it was thought better to have a short measure dealing with that class of case alone. The last visit paid by their Excellencies before leaving Belfast on Thursday was also one in the interests of public health, as it was to the Model Dairy established by Mr. Alec Wilson at Belvoir Park. The precautions taken to ensure the purity of the milk are as follows:—(1) The employees are inspected by a medical man, to ensure their being free from infectious disease; (2) The cows are systematically inspected by a veterinary surgeon, are properly housed, and are milked in the cleanest possible way; (3) The milk is at once chilled, to stop the growth of bacteria, then filtered through prepared cotton wool, bottled and sealed; (4) All utensils are properly washed and scalded with high-pressure steam immediately after use. Mr. Wilson contemplates the further step of testing all cows by the tuberculin test, if the public is willing to pay the higher price which this would render necessary, but at present the matter has not been settled.

Notification of Births.—At a meeting of the Public Health Committee held last week, the Medical Superintendent Officer of Health recommended bringing into operation the "Act to provide for the Early Notification of Births," and the Committee agreed to recommend the Corporation to do so. This will entail on all doctors and midwives who have seen a woman within six hours of her confinement the duty of sending information of the same to the Public Health authorities within 36 hours. For this work no remuneration will be given, though a supply of stamped postcards will be generously given to those who apply for them! No doubt the medical members of the Corporation will have something to say before the Act is finally adopted.

LETTERS TO THE EDITOR.

SOUTHEND AND CHELTENHAM.

To the Editor of The Medical Press and Circular.

Sir,—Southend and Cheltenham do not stand alone. The administration of sanitary laws throughout the country is everywhere more or less defective; in many places the laws are virtually almost completely ignored. This fact was illustrated within the past few weeks in the Local Government Board's report on 30 Lancashire boroughs and urban districts. In many of these places no medical officer is employed, and where a sanitary inspector is engaged he is often paid to devote only an insufficient part of his time to the work. Although overcrowded slum-dwellings are common, and outbreaks of infectious diseases frequent, no isolation accommodation is, as a rule, provided; whilst although the councils are largely made up of tradesmen, the Adulteration of Food Acts are mostly ignored. The offences of the Southend and Cheltenham authorities, in merely treating in the most scurvy fashion possible their medical officers, must be, in comparison, looked upon as quite venial. For all such offences the councils are held solely responsible. Over and over again, and as late as Tuesday, October 22nd, *The Times* (which, whatever its faults, remains still the great leading paper) has denounced local authorities in scathing terms. It charges them with "placidly obstructing, while the poor, who are unable to protect themselves, die of small-pox, of enteric fever, or of diphtheria; and while the children, whom it would be the first duty of a patriot, or of a statesman to protect, are left to waste their strength in struggles against preventible diseases which effective administration would speedily banish from the country." The main object of my letter now is to point out and emphasise the fact that if the direct blame may be fairly cast upon these inferior authorities the real blame and the greater shame rest upon the great body of citizens and ratepayers who put them in office or allow them to continue there when proved incompetent. No effective remedy for existing evils can be found unless the spirit of local and imperial patriotism can be roused. One would think this should be possible at least in a place like Cheltenham, a wealthy residential town, the seat of a great public school, and numbering among its citizens probably more capable men of leisure than are to be found in any other similar city of the same size. Even at places like Southend, which seem to exist mainly as cheap holiday resorts for Cockney trippers, it might be thought that the inhabitants would recognise their duty towards their town and their country. It might be thought they would recognise that the greater part of the misery due to sanitary maladministration falls upon the poor; that high infantile mortality is only a measure of the injury inflicted upon the survivors who struggle through, and that without an exuberant population, physically, mentally, and morally of the highest quality, the nation cannot prosper, the Empire cannot be maintained. Lastly, it is amazing to see the apathy of the responsible classes in face of a tremendously active socialistic propaganda that finds ample means at hand to stir the popular discontent in merely pointing to the evils which, owing to the selfish indifference of the wealthy, leisured, and cultivated classes, the poor are condemned, unheeded, to endure.

I am, Sir, yours truly,
SANITARIAN.

October 25th, 1907.

ADMINISTRATION OF ANÆSTHETICS FOR UNQUALIFIED DENTISTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—All who believe in protecting qualified practitioners in the exercise of their profession, and in protecting the public from the unqualified, must cordially approve of the exertions of the Irish Branch of the British Dental Association, to which you refer in an editorial note in your last issue. As you say, however, the practice is hardly of such important dimensions as the Association seems to imagine, and offenders can be easily dealt with by the General Medical Council or by the licensing bodies which have granted their qualifications. There seems, on the other hand, to be no protection either for the public or the medical profession against a practice more detrimental to the common good, and much more widespread. I mean the practice adopted by dentists, most of whom are not medical men, of themselves administering anæsthetics. Still worse is the custom, also stated to be widespread, of a mechanical assistant administering the anæsthetic, while his principal operates. Nowadays it is very rightly pointed out that even medical men are hardly sufficiently trained in the administration of anæsthetics; nevertheless, dentists and their unqualified assistants, without any training whatever, are willing to take the responsibility from which some qualified medical men will shrink. The large number of deaths which take place in the dentist's chairs is sufficient justification from the public point of view for calling attention forcibly to the matter. It should be penal by law for anyone but a qualified medical man to administer an anæsthetic. The British Dental Association might make a start by forbidding it to any of their members who are not medical men.

I am, Sir, yours truly,
CRITICUS.

VIVISECTION COMMISSION DIFFICULTY.—"KILKENNY CATS."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am interested to read your opinion that a committee composed of "Mr. Coleridge, Miss Lind-af-Hageby, Miss Beatrice Kidd, and Dr. Hadwen" would, after sitting a month, end in a tragedy similar to that of the Kilkenny cats. If your assumption were true, it might be in the best interests of the vivisectors to appoint such a committee, as it would furnish a short and easy method of getting rid of us. However, why the three last named should be groundlessly accused of mutual animosity absolutely passes my comprehension. May I explain that in the anti-vivisection world there is but one division—that between the abolitionists and the restrictionists, the latter party being represented by Mr. Coleridge. As this gentleman has informed the Royal Commissioners that he "wishes to secure the continuance of research," and "trusts that nothing will be done to hamper the legitimate employment of the method," he can hardly be called an anti-vivisectionist at all, therefore we have, on the side of the anti-vivisectionists, a happy family party remaining; and if the methods of the Kilkenny cats be adopted by those outside our circle, we are not concerned. Real anti-vivisectionists, I need hardly say, would not consider an increase of the inspectorate as any safeguard to vivisected animals. They remember the late Professor Lawson Tait's earnest warning, which history has so amply justified —"Combine to abolish the medical inspector." The vivisectors and Mr. Coleridge might welcome such a change; anti-vivisectionists would not, or would they regard it in the light of a "concession" to their demands.

Yours, etc.,
BEATRICE E. KIDD,
Secretary British Union for Abolition of Vivisection.

November 2nd, 1907.

A QUESTION OF PROFESSIONAL ETIQUETTE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I should be glad to have your opinion on the ethical aspect of the following announcement which appeared under the heading of "Court News" in the *Times* of October 24th, 1907:—

"Dr. J. Leon Williams, who has recently been made a Membre Honoraire of the Société Odontologique de France, 'en reconnaissance des éminents services rendus par lui à la Science Odontologique,' has returned to 30, George Street, Hanover Square, after several months' absence, in greatly improved health."

According to the latest *Dentists' Register*, this gentleman is an L.D.S.I.

Yours, etc.,
ENQUIRER.

[In reply to the inquiry of our correspondent as to the ethical aspect of this announcement, our opinion would depend on the way the announcement was brought about. The gentleman referred to may be the victim of journalistic officiousness. If, however, done with his knowledge, it is unquestionably a form of advertisement to be deprecated.—ED. M. P. AND C.]

WE are asked to announce that a Conference of Representatives of Sanitary Authorities will be held in the Council Chamber, Caxton Hall, Westminster, at 11 a.m. on Friday, Nov. 15th, for the purpose of considering the question of the establishment of a Supreme National Health Authority. Already the responses to the invitation to the Conference have been numerous and cordial, and the meeting promises to be a great success.

SPECIAL ARTICLE.

ANNUAL REPORT OF THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

THE annual report of the Council has been sent to those Fellows and Members whose names are enrolled on the list of those to whom the report is sent annually. Any Fellow or Member may have the report sent each year from the College by applying to the Secretary. The report will be laid before the annual meeting of Fellows and Members at the College on Thursday, November 21st, at three o'clock p.m.

Direct Representation.—The question of direct representation of Members on the College Council is fully dealt with in the report, and includes the memorial of the Society of Members to the Prime Minister, together with the observations thereon by the Council of the College. The rejoinder to these observations by the memorialists is also published, and a statement by the deputation of Members of the College Council, together with some additional remarks made by the deputation when it was received by the Lord President of the Privy Council.

The question of admitting women is also dealt with, and the petition, having 2,792 signatures in reference thereto, is included. Counsel's opinion has been obtained on the points raised by the petitioners, and it has been ascertained, (*a*) that the Council have no power under the charters of the College to admit women to examination for the diplomas of the College, but that they have that power under the Medical Act of 1876; (*b*) that the Council can, if they think fit, admit women to examination for the diploma of Member, and decline to admit them to examination for the diploma of Fellow; (*c*) that a woman, admitted a Fellow or Member under the Act of 1876, would not be able to take any part in the government, management, or proceedings of the College by reason of obtaining a registrable qualification under the terms of the Act. Having satisfied themselves upon these points, the Council adopted the following resolution: "That, in the opinion of the Council, it is desirable that women be admitted to examination for the diploma of member." It was decided that, before taking a poll of the Fellows and Members upon the question, the Royal College of Physicians should be approached, in order that it might be ascertained whether that College would be willing to admit women to the Conjoint Examinations. Communications upon the subject have accordingly been addressed to the Royal College of Physicians, but their final reply has not at present been received.

Appointment of Assessors.—The Royal Colleges recently expressed their willingness to appoint assessors to the examinations conducted by the London School of Tropical Medicine, of students who have followed there or elsewhere a course of instruction approved by the two Colleges, and to grant to such candidates as may hold the diplomas of the Royal Colleges, and who are approved by the examiners, certificates endorsed by the aforesaid assessors. In pursuance of this scheme, Dr. H. H. Tooth, C.M.G., and Mr. A. G. R. Foulerton have been appointed assessors for the year ending June, 1908.

Vivisection.—The College having been offered the opportunity of giving evidence before the Royal Commission on Vivisection, the president, Mr. Henry Morris, was appointed by the Council to appear before the Commissioners as the College representative. The president gave his evidence in May last. The Council at the same time expressed the opinion that the Act of 1876 was sufficient protection against any abuse of vivisection, and "earnestly hoped that the progress of surgical science would not be hindered by further restrictive legislation."

Miscellaneous Items.—The number of diplomas issued during the period with which the report deals is as follows: Membership, 435; fellowship, 49; licence in dental surgery, 76; and the diploma in public health, 25. The attendance of members of the Council at the various committees held at the College during the past year is included, and it is interesting to notice that the president and vice-presidents were summoned to no fewer than 69 meetings, besides the usual monthly Council meetings. Extensive and valuable additions to the series of tumours of the brain have been presented to the college museum by Mr. C. F. Beadles, and a series of specimens from the same donor illustrating aberrations in the distribution of the cerebral arteries. Many valuable preparations of the viscera of the Port Jackson shark have been made from material presented by the Government of New South Wales and by Professor J. P. Hill. During the past collegiate year the supply of books and journals in the library has been well kept up, and the number for this period has been 11,090. The College obituary list includes 3 honorary fellows, 25 fellows, and 292 members.

THE PROPOSED MEDICAL SERVICE FOR THE TERRITORIAL FORCE.

SIR ALFRED KEOGH, Director-General of the Royal Army Medical Corps, addressed a meeting of the medical profession in Manchester during the past week, and explained at length the nature of the War Office's proposals for the medical arrangement of the Territorial Force. He said that the scheme which he was to explain was not by any means new, seeing that it was drawn up about at the time when he became Director-General, but had been held in abeyance till Mr. Haldane had considered the general arrangements for the organisation of the Volunteers. The medical service of the Volunteers, he remarked, was utterly inadequate either under the territorial army system or under the Volunteer system to perform the duties which are required of it in time of war. He knew that a great many people say, "Oh, when war breaks out you will get lots of doctors" but "lots of doctors" won't do. There is a differentiated function for the Army medical officer. He has not only to see to the curing of disease and the healing of wounds, but he is an administrator and organiser, and the better business man he is the better officer he is. All these things are compatible with a very definite love for and pride in his profession. He explained that when war broke out, what Mr. Haldane described as the expeditionary force would be able to leave the country, taking the regular medical service with it. The defence of England would then rest with the territorial force, and the medical equipment of this defence would fall on the medical profession. The duty of the medical profession in connection with an army was to maintain the strength of the fighting force in the field. That was the primary, almost the only, duty, because it included all the minor duties. In one year the strength of an army in the field diminished by 80 per cent. A large part of that diminution was due to disease, and it was the business of the medical service to see that disease was prevented and to see that no one was allowed to leave the force unless there was the strongest possible reason for his going. If the medical service determined that 3,000 or 4,000 or 5,000 men must leave the fighting area no one could say "Nay," so that such decisions entailed an enormous responsibility. In the field ambulances there was something entirely new in the British Army, but something that had proved a great success in the Russo-Japanese war. From the time that wounded men were picked up and taken to the field ambulance they would remain in charge of the medical staff; they were received, clothed, fed, paid, and where necessary sent home to England by the medical staff. This meant that an enormous work fell upon the medical profession. In an army of 100,000 men there would be always about 10,000 in the custody of the medical department. These 10,000 would have to be rigorously scrutinised as to the absolute necessity of their being transported home. One of the failures of the South African war was that many men came home to England who never should have come. In every one of the hospitals under the new scheme each patient would be watched carefully and sent back to his battalion if possible. Another new feature of the scheme was the provision of a sanitary service for an army in the field. Each division would have its special sanitary department under the charge of an officer with special knowledge of sanitation—a man whose whole time was given to sanitation in peace and in war, and whose business it was to see that the health of the troops was guarded. A school of sanitation had been established at Aldershot where men were being carefully taught for every battalion. At the manœuvres these men had had further experience of the work expected of them, and he was glad that reports received from the manœuvre areas were very satisfactory; in time of war he would like to flood the Army with military and civil sanitarians, and endeavour to prevent the decimation of battalions by disease. Turning next to the Volunteer army, he said the territorial scheme was a scientific scheme, and would, he hoped, effectually grapple with the deficiencies and anomalies of the now defunct volunteer medical system. We must, remarked the Director-General, have some arrangement by which the medical profession can devise a system of disease prevention, hospital organisation, and so on. He recognised that the medical profession is in a position of special difficulty with regard to volunteering. Under the old system the medical man had to go into camp every year, had to go through a certain course of instruction, and so forth. He held that it is only necessary for people to go into camp to undergo any training in peace who do not in civil life perform those duties which they would be required to perform in connection with the volunteer army. Surely the medical officer of health of a county or great town can learn nothing from us in time of peace concerning sanitation. These men should not have been excluded from the volunteer army; there should have been a place for them, some method by which the country could have the great benefit of their service and experience, without putting any burden upon them in time of peace. That is one of the principles he desired to lay down. But, of course, there are certain duties to be performed by medical men who join certain branches of the medical corps in connection with ambulances and hospitals which must be learned. Sir Alfred went on to explain that he proposed two medical officers for each volunteer battalion and that each officer should go into camp every two years. Even there, he said, I do not wish to impose difficult conditions. I say that even if the officer cannot go into camp in the year when it comes to his turn he need not. The conditions are such that his explanation of inability to attend would be accepted; but he would be asked to do something else—to assist in some way in furthering the volunteer movement in his own time during the year that would be left to his own good faith. In further explanation, he said that he proposed a consolidated medical corps for the territorial force, which meant that the medical profession would combine in one great organisation for the two classes of work which he had outlined—viz., hospital work and sanitary work—that the organisation should be an exact reflection of the medical corps of the regular Army, with a principal medical officer in each area derived from the volunteer medical service, that a staff officer should be selected from the Royal Army Medical Corps to assist the principal medical officer, and that at the headquarters of each "area" a military medical school should be established with a specially appointed adjutant and staff of instructors. At these schools officers could gain their certificates and be saved the time and trouble of journeys to Aldershot. We have, he said, no hospitals of any kind in the Volunteers, and I wish, in accordance with the principles I have enumerated, to raise the staffs of those hospitals in time of peace. I ask that the great physicians and surgeons in centres like Manchester and Liverpool should join the territorial force, not to undertake any duties whatever in time of peace, but to undertake specific duties in time of war. I do not ask them to leave their own towns. The principle here would be of sending sick and wounded to the hospitals. I propose to establish in connection with Manchester a large general hospital—a military territorial army hospital—which in time of war would work in conjunction with the troops in the neighbourhood. They could do this work without interfering with their private work or their work in hospitals. Sir Alfred added in conclusion, that the appeal which he made to the surgeons and physicians he extended also to the sanitarians of the country—the medical officers of towns and counties. He wanted a sanitary officer for each division in time of war. He was also hoping to raise a nursing service, and had already received much encouragement from the matrons of hospitals.

A cordial vote of thanks to the Director-General concluded the proceedings.

REVIEWS OF BOOKS.

POST-GRADUATE STUDIES. (a)

This collection consists mainly of papers read by the author at various medical meetings. He has been led to publish them in book form because he believes the subjects dealt with may prove of interest and service to a wider circle. The volume contains altogether nine clinical dissertations. Most of these deal with questions of diagnosis such as that of subphrenic abscess, pleural effusion, disseminated sclerosis, cerebral hæmorrhage, and acute endocarditis. One very interesting and instructive paper is that dealing with the naked eye examination of the fæces as an aid in the diagnosis of disease. It is, as the author remarks, too often neglected by the medical attendant. He tells of two cases, one a club patient who has run to earth by having his stools examined when they were found to be normal; and the other who was found to be suffering from malignant disease of the rectum. The author treats the subject under four distinct headings, viz., the amount, the colour, the consistence and general characters, and lastly the presence of abnormal constituents.

The last paper in the book is on the subject of syphilis in the Army. This gives a very exhaustive account of the matter, and is fully illustrated by means of several carefully compiled charts. Incidentally, however, we do not think so many charts should have been included as they tend to swell out the volume to almost one half the size covered by the text proper. The treatment of syphilis as it occurs amongst soldiers is very fully given, and is largely based on Mr. Alfred Cooper's ideas as set forth in the latter's work on this disease. The tables given will be found very useful for reference and comparison.

With regard to the other papers we need not enter into details. They have all of them reference to subjects of every-day practical importance, and will be of the greatest help to the busy practitioner who is on the outlook for fresh knowledge regarding the diseases of which they treat. Such a volume as this forms an excellent supplement to the ordinary textbooks of medicine, and for this reason we congratulate the author on its publication. The style is distinctly interesting and free from technical phraseology, so that the volume forms quite pleasant as well as instructive reading. It will doubtless find a place among the ever-increasing works and monographs on medical subjects. It is certainly well worthy of careful perusal by all who are seekers after knowledge.

WHAT TO DO IN CASES OF POISONING. (b)

No words of ours are required to commend this well-known pocket guide. It has been thoroughly revised, restored, and renovated, to use the author's own facetious language. A great deal of new matter has been introduced into this, the tenth edition. Dr. Murrell's name has become known to every student and practitioner of medicine through this excellent little treatise, without which we doubt if we should be able to cope with poisoning cases so well as we do. The author is witty and sarcastic at the same time, and his ready wit makes his remarks strike home in a way which few writers can achieve.

(a) "Post-Graduate Clinical Studies for the General Practitioner; First Series." By H. Harold Scott, M.D.Lond., M.R.C.S., L.R.C.P. Fellow of the Royal Institute of Public Health, late Medical Officer in charge of Hospital for Women and Children, etc. London: H. K. Lewis. 1907. Demy 8vo. Price 8s.

(b) "What to do in Cases of Poisoning." By William Murrell, M.D., F.R.C.P., Physician to the Westminster Hospital, Tenth edition. London: H. K. Lewis.

The various poisons are arranged alphabetically so that reference is quite an easy matter. It is quite interesting to find antipyrin and many other drugs, all of which can now be readily got in tablet form, referred to as being distinctly dangerous and very often giving rise to symptoms of poisoning when taken indiscriminately by the ignorant public. Thus sulphonal, veronal, and substances of a similar nature, in these days frequently used by laymen without medical advice, are mentioned as being poisons. The perusal of Dr. Murrell's book would doubtless terrify the drug-taker, while it should teach the general practitioners the dangers of administering drugs in tablet form. This edition is sure to be as popular as its predecessors. It is certainly very comprehensive and accurate in detail.

ON DIAGNOSIS IN URINARY SURGERY. (*a*)

"This little book describes the principal modern methods of localising and distinguishing those diseases of the urinary organs which are usually assigned to the surgeon." Perhaps the author will forgive us if we suggest that this sentence does not exactly convey his meaning, and that if the word "patient" was substituted for "surgeon" the sentence would be more gramatically correct.

The little work consists of four chapters. The first deals with the interpretation of urinary symptoms; the second with abnormal conditions of the urine; the third with the physical examination of the patient and of the urinary organs; and the fourth with the differential collection of specimens of urine. A curious point about the last chapter is that, though Nitze's inspection cystoscope is described fully in the previous chapter, in this one, which deals with the differential collection of urine, there is no mention made of Nitze's combined cystoscope and ureteral catheter. This instrument is, however, very much the easiest means of obtaining specimens of the urine from each kidney separately, and is far more exact than is Luy's segregator.

The book, however, gives, on the whole, an excellent introductory description of several methods of diagnosis in urinary surgery.

ON PRESCRIPTION WRITING. (*b*)

This is a most concise little work on prescription writing, and fully justifies its existence. Although it is short, it is most complete, and will be found invaluable to the student—in America. Unfortunately for the English student, the book is based on the American Pharmacopœia, and so, as far as dosage is concerned, would lead to confusion.

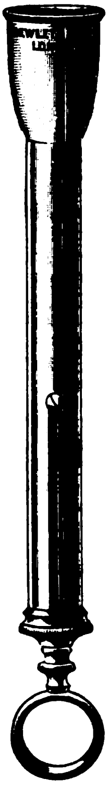
There is a handy list of mis-pronunciations of common occurrence, and also a list showing the pronunciation of pharmacopœial terms. So far as we have examined it, we have only noticed one mistake. Surely the pronunciation of cochleáre is as we have marked it, and not as Dr. Mann would have it—cochléare.

THE LAWS OF HEALTH. (*c*)

Hygiene as it affects the school child is a very complex subject, including, as it does, so many sciences of diverse characters. It is now universally recognised that the school teacher should be acquainted with the rudiments of the subject, and for the purposes of a text-book for such the volume under consideration is to be commended. The author is extremely well acquainted with his subject, and has shown excellent judgment in his selection of the matter incorporated, so that the teacher is provided with essential information. Particular mention must be made of the chapter on Physical Exercises, which includes a short dissertation on the anatomical principles underlying them, while that on Corporal Punishment is by no means the least important. We agree with the author that chastisement should only be administered for the graver faults, and for this purpose the instruments least likely to injure the offender are stated to be the birch and the tawse. Altogether the book is admirable, and can with propriety be commended not only to teachers but also to medical practitioners, who will find in these pages much useful matter.

NEW SURGICAL APPLIANCE.

NEW CUPPING INSTRUMENT FOR CERVIX UTERI.



The illustration represents a simple instrument designed by me, and neatly made by Messrs. Hewlett and Son, Charlotte Street, E.C. I find it useful for dry or wet cupping of the uterus, and by the latter proceeding I have been able to give speedy relief to the vertical headache so often complained of by women during the menopause. It will also remove unhealthy secretions from cervical canal in conjunction with the use of my wire curette, and thus prepare the part for the usual application of liquid escharotics or astringents, hastening the cure considerably in cases of chronic endometritis, etc. It will also be found useful during the operation for supra-vaginal amputation by drawing down the cervix, where the parts may be too soft and friable to be held by volsella. The cup is simply pressed well up on cervix, the central rod drawn down, and a half-turn of ring at base will throw projecting pin into angle of slot, and procure the vacuum in cup. This can be left on as long as required. The simplicity and handiness of the cervical cupper should, I think, recommend it for the purposes named, but no doubt many others will be suggested to the gynæcologist.

Alexander Duke.

MEDICAL NEWS IN BRIEF

Engineer's Death.—Conflict of Medical Evidence.

On the 10th ult., at the North Shields County Court, Elizabeth Davison claimed from Richard Irvin, steam trawler owner, £300 compensation for the loss of her husband, John Davison, an engineer on board the steam trawler Mercia, who died at sea on July 14th. Davison, counsel explained, was 34 years of age, and left five children, the oldest of whom was 11. While the vessel was off St. Abb's Head on July 14th he was found at the foot of the engine-room ladder in a dying condition. He had previously suffered from epilepsy, and had been operated on for that, but Mr. Morgan claimed that death was the result of an accident. Dr. Mears, who had known Davison for seven or eight years, spoke to performing the operation of trepanning for epilepsy on May 20th last, and to certifying him as fit to follow his employment on July 6th. He also described the post-mortem examination, saying that there was a large bruise about the size of a saucer on the top of the head, the scalp being knocked into a pulp. He gave his opinion that death was due to concussion of the brain or shock to the nervous system, caused by a fall down the ladder. There was, however, he admitted, no visible injury to the brain or skull, and no hæmorrhage.—Dr. J. H. Hunter, assistant surgeon at the Ingham Infirmary, South Shields, also agreed that concussion might have been caused without any visible injury to the brain, and this view was supported by Dr. Gowans, South

Shields. For the respondent, however, Dr. Lochland Frazer, of North Shields, who conducted the post-portem examination, said death was obviously due to natural causes. There was no fracture of the skull, no hæmorrhage of the brain, and no laceration of the base of the skull, but the aortic valve was incompetent owing to the heart being dilated. Death was either due to epilepsy or heart failure.—Dr. Morrison, senior surgeon at the Royal Infirmary, Newcastle, expressed the opinion from hearing the evidence that death had resulted from nothing but natural causes. If death was due to concussion there would be a bruise on the brain.—Summing up, the judge commented on the difficulty of arriving at any facts at all. The only undoubted fact was that Dr. Frazer found in the post-mortem examination what he said was amply sufficient to cause death. There was no evidence that the heart affection was accelerated by the fall, and he gave his award for the respondent.

Unregistered Dentists Fined.

AT Old Street, prosecutions by the London and County Medical Protection Society (Limited) brought before the Court three persons—H. M. Hanreek, Bethnal Green Road; Joseph Lechan, Whitechapel Road; and Joseph Weinberg, Whitechapel Road—for contravening the Medical Act, 1878, by using styles and titles implying that they were registered dental practitioners under the Act. Mr. G. H. Young prosecuted; and evidence was given by Mr. Hugh Woods, M.D., Secretary of the prosecuting society, Craven Street, Strand, as to visiting the business premises of the respective defendants. Mr. Hanreek exhibited at his shop, which was also a hairdresser's shop, the name "H. Hanreek, surgeon dentist," above the door, and inside "G. Hanreek, practical dentist." The defendant Lechan, who is also a chemist, exhibited the words "surgeon dentist"; but Weinberg only exhibited a frame with the word "dentist" and a mass of teeth in the window. Mr. Percy Robinson, defending Hanreek, said the signs were put in in the time of his client's father, who was a registered dentist, and they had been left since his death in 1889. He had no idea he was infringing the Act. The defendant Lechan, defending himself, said he was qualified in Vienna and Berlin, and thought the qualifications were sufficient in England. Mr. A. J. David, defending Weinberg, submitted that the use of the word "dentist" alone was not any claim to be a registered dentist. Mr. Cluer overruled the point. He fined the defendants Hanreek and Lechan each the full penalty of £20 under the Act, and further to pay each three guineas costs. In consideration of the defendant Weinberg's having been carrying on his business since 1872, before the passing of the Medical Act, the magistrate imposed half the fine, £10, with three guineas costs.

Bogus Dentists in Ireland.

THE campaign started by the Irish Dental Association against bogus "dentists" has resulted in the case of the Attorney-General, at the relation of Kevin E. O'Duffy v. Henry J. Bradlaw, surgeon dentist, Limited, and eight other defendants, which was concluded during the past week in the Dublin Courts. The relator asked for an injunction restraining the defendant company, who carried on business in Dublin, from advertising for custom under the description of "surgeon dentist" or any other description calculated to induce the public to believe that such business was carried on by duly registered dentists. The defendants denied any conspiracy to deceive the public in the formation of the company, and stated that seven of the defendants, who signed the articles of association, were all, at the date of registration, registered as dentists under the Dentists' Act, 1898. They also denied that any wrong had been committed on the public. Since the action was instituted the defendant company had changed their trade name to that of "Henry J. Bradlaw, Limited." The Master of the Rolls, in giving judgment, said that all the time the action was instituted the directors and shareholders of the defendant company were, as stated by an eminent judge in another case, an audacious fraud upon the public. The names and style and title of the company was a false representation, and was scattered broadcast through the land. It was not necessary for the relator to prove that anyone incurred loss. Mr. Bradlaw might be an excellent worker—as good, perhaps, as any medical practioner, who had not been instructed in dentistry—but the Act of Parliament was clear on the point as to his right to describe himself as a surgeon dentist. He granted the injunction asked for, restraining the defendant company from describing their business in such a way as to lead the public to believe that their business was carried on by a person, or persons, registered under the Dentists' Act, 1898. He also granted an injunction, restraining the defendant company and its members from using the title dentist, either alone or in combination with any other word or words in the memorandum of association, or any returns or documents filed pursuant to the Companies Acts, with the Registrar of Joint Stock Companies.

Royal College of Physicians of London.

AT the ordinary quarterly *Comitia* of the College, held on Thursday last, Daniel Colquhoun, M.D.Lond., of Dunedin, New Zealand, and Edward Rennie, M.D.Lond., of Sydney, Australia, were admitted, *in absentia*, to the Fellowship. Dr. F. W. Andrewes was elected a member of the executive committee of the Imperial Cancer Research Fund, *vice* Sir William Broadbent, deceased. Dr. Frederick Taylor was re-elected a member of the Committee of Management of the Examining Board in England. W. H. Price Saunders, late a student of Epsom College, was, on the recommendation of the Presidents of the two colleges, appointed Jenks Memorial Scholar.

Medical Man Accidentally Shot.

WE regret to announce that Dr. Vining Paul, a young Harwich medical man, was the victim of a curious fatal shooting accident at Ramsey, near Harwich, recently. He had been rabbit shooting with some friends, and, the sport having finished, the guns were placed in a motor car in readiness for the return journey. By some mischance one of them was left loaded and cocked, and, just as Mr. Paul was stepping into the motor-car, a dog jumped and touched the trigger. The charge entered Dr. Paul's body, passing through the left lung, and he died on Friday evening. Dr. Paul, who was only 28 years old, came to Harwich in January of the present year, and had previously held an appointment at Taunton Hospital.

Royal Army Medical Corps.

MAJOR H. S. PEEKE has been granted six months' leave out of India on medical certificate.—Captain F. A. Stephens has assumed medical charge of Staff and Departments, Scottish Command, vice Captain V. J. Crawford, transferred to the Southern Command. —Lieut. J. A. B. Sim assumed charge of the Military Hospital, Berwick-on-Tweed, on the 1st inst., vice Captain F. M'Lennan, who takes charge of the Military Hospital, Aberdeen, during the absence on leave of Major A. O. C. Watson.

The Royal University of Ireland.

AT a meeting of the Senate of this University held on Thursday, October 31st, the following resolution was passed by a majority:—"That it is expedient for many reasons that the conferring of degrees in this University should be confined to the purely Academical Ceremonial, as it is in the University of Dublin and elsewhere." Presumably as a result of this resolution, the National Anthem was omitted from its usual place at the termination of the Degree-giving Ceremonial, which was held the following day.

Trinity College, Dublin.

THE following candidates passed the Final Medical Examination (Part I.), Michaelmas, 1907:—David J. Miller, Edward J. H. Garstin, Alex. K. Cosgrave (Passed on High Marks), William A. Nicholson, Richard J. Attridge, William H. Sutcliffe, Harold S. Sugars, Edwin B. Bate, James E. M'Causland, James D. Murphy, Richard D. FitzGerald, Howard S. Millar, Frederick R. Sayers. Intermediate Medical Examination (Part II.).—Henry H. James, Walter E. Adam, Victor W. T. M'Gusty, Hans Fleming, William H. Hart, Denis J. Stokes.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

The Habitual Vomiting of Nursing Infants.—Peiser (*Berlin Klin. Woch.*, July, 1907) recognises three forms of habitual vomiting in infants. The first occurs in healthy appearing babies, who receive too much food at one feeding, or are fed too often, or the milk is too rich in fat. These cases are easily controlled by regulating the amount and the number of the feedings, or by cutting down the fats. A second form occurs in children who, though apparently well nourished, are of nervous temperament, awake easily, cry much, and are easily irritated. Here the vomiting occurs from two to four hours after feeding, when normally the stomach should be empty. Often in this class of cases laryngismus stridulus or tetany occurs. In certain families, with marked neurasthenic tendency, all the children are subject to this form of habitual vomiting, which is extremely resistant to treatment, and finally disappears spontaneously. The author considers this form to be due to a pyloric spasm, more easily excited in such highly-strung children. The third form occurs in badly nourished, weak infants, and is more a regurgitation than an actual vomiting. In observations on such children with the X-ray, the stomach was dilated, and the period of gastric digestion prolonged. The vomiting in this latter class of cases takes place three or four hours after feeding. The cause is probably a weakness of the musculature of the stomach, and particularly of the cardiac orifice, which allows of a regurgitation of food. The treatment of this third form is general, and not until the general condition of the child is normal will the regurgitation disappear. D.

Nucleinate of Soda in Peritoneal Infections.—Chantemesse and Kahn (*Bull. de l'Acad. de Méd. Paris*, July, 1907) have found that nucleinate of soda, 1 to 100, injected hypodermically, at once arouses a rather lasting increased phagocytic action in peritoneal infections. In two cases they have even seen the classic symptoms of typhoid perforations ameliorated to such an extent as to render operation hopeful, by the two or three injections given from fifteen to eighteen hours after the first signs of the perforation. The patients refused operation, dying twelve days later of slow peritonitis, and the autopsy revealed a very marked defensive leucocytic and connective tissue process in the abdomen, the large perforations being almost thoroughly obliterated. They see a decided utility in the action of the drug in such conditions, and one not limited altogether to peritoneal inflammations, as they have seen it of value also in erysipelas and pneumonia. The reaction is moderately severe, which is to some extent a drawback. D.

The Gastric Secretion in Nephritis and Dechloridation.—Enriquez and Ambard (*Semaine Médicale Paris*, August, 1907) have found that deprivation of salt in diet seems to have a levelling effect on the gastric secretion. In both hyperchlorhydria and hypochlorhydria the absence of salt from the diet brought the gastric secretion to practically a uniform level, very close to normal. Their tests further demonstrated that every nephritis, even the latent form, has a marked influence on the gastric secretion. When there are merely traces of albumin or even simple arterial hypertension in the kidney, hyperchlorhydria is observed. It is probably, they state, the result of the excess of salt in the organism, salt being the general stimulant *par excellence* of the gastric secretion. Retention exaggerates the gastric secretion, while deprivation of salt reduces it. On the other hand, in nephritis with albuminuria, the retention of it seems to irritate the stomach mucosa just as it irritates the kidney lesion. In this case the stimulating action of the salt is overcome by its irritating, and therefore depressing action, with hyperchlorhydria as the result. But for the same reason that deprivation of salt has a beneficial action on the excessive secretion, it also has a beneficial action on the deficient secretion. Deprivation of salt allows the stomach mucosa to recover its tone even before the general salt balance throughout the organism is restored, and thus dechloridation is liable to be followed by a brief, transient hyperchlorhydria. The effect of salt starvation on perverted secretions opens, they state, a new field for the study of the pathology of the stomach, while at the same time it suggests a rational mode of treatment for many forms of gastric affections which at first glance seem to have no connection with each other. D.

Acute Yellow Atrophy of the Liver in consequence of Chloroform Anæsthesia.—(*Arch. f. Klin Chir.*, Berlin, 1907). Galeke's patient was a robust young woman, on whom a herniotomy, lasting half-an-hour, was performed, under 25 c.c. of chloroform. The anesthesia was unusually smooth; hernial sac contained only omentum. Jaundice and cholemia developed in less than 24 hours, and at the end of 92 the patient died in coma, after delirium and convulsions. The microscope revealed extreme destruction and fatty degeneration of the cells in the liver and in the convoluted tubules in the kidneys. The chloroform was evidently responsible for the trouble, as infection and thrombosis could be excluded. The same chloroform, used for other patients the same day, caused no by-effects in other cases. All the similar cases of yellow atrophy of the liver on record, following administration of chloroform, terminated fatally in from three to six days. The patients were generally young and robust. It is noticeable that the operations had always been abdominal, and that the patients were moderately or extremely fat. Other facts are cited which suggest that an unusually fat liver is less resistant to chloroform than one less so. D.

Examination of the Fæces for Occult Blood.—Goodman (*Amer. Journ. Med. Sciences*, Oct., 1907) discusses the value of the various tests for recognising the presence of blood in the fæces that is not evident to the naked eye. The test which Goodman has found most valuable is a modification of the benzidin test of O. and R. Adler. It is performed as follows: A concentrated solution of benzidin is made by using as much benzidin as will go on the end of a knife in about 2cc. of glacial acetic acid. A small piece of fæces about the size of a pea is suspended by stirring in a test tube, one-fifth full of water; the test tube is closed with cotton wool and the contents boiled. Ten to 12 drops of the benzidin solution are poured into a test tube, and from 2.5 to 3cc. of a 3 per cent. H_2O added. To this then are added from 1 to 3 drops of the boiled fæces, and in the presence of blood the colour becomes green, blue-green or blue, according to the amount of blood present. Even with very small amounts of blood the colour change is completed in about two minutes. If there is no blood present the colour is unchanged. Goodman has used this test extensively, and finds it very reliable under certain restrictions. If the test is negative one can be quite sure that no blood is present, but if it is positive the result should be confirmed by some other test. It is of great importance that all disturbing factors should be removed before the test is applied. Goodman advises that if the fæces show a positive reaction for blood, another stool should not be examined until the diet and medication have been regulated. K.

Early Diagnosis of Cancer of the Stomach.—Stone (*Amer. Journ of Med. Sciences*, Oct., 1907) analyses the various forms of evidence on which an early diagnosis of cancer of the stomach can be made. He dwells on the importance of remembering that cancer of the stomach can no longer be looked on as a rare disease in patients under 35 years of age. The earliest symptoms are those of simple dyspepsia coming on some hours after a meal and during the height of digestion, and he agrees with Boas that these symptoms are usually vague and indefinite in their onset. The ultimate diagnosis, of course, rests on the physical examination of the stomach and its contents. Free HCl. is absent in from 90 to 92 per cent. of the cases, and this, combined with the presence of the Oppler-Boas bacilli, is of the greatest importance in the diagnosis. The detection of what is called occult blood in the stools and stomach contents is also of very great importance. Such hæmorrhages are never found in healthy individuals. The blood is detected by the benzidin test, and it is said that it is present in practically every case of cancer of the stomach. In applying this test it is important that no meat or raw vegetables should be eaten for two or three days before the stomach contents and fæces are examined. Stone urges the adoption of Mayo's maxim that "a suspicion of cancer of the stomach, which cannot be disproved by known methods within a short time, should lead to exploration." K.

Bier's Hyperæmia.—MacLennan (*Practitioner*, Oct., 1907) describes this method of treating microbic invasions. In treating lesions of the limbs all that is necessary is the application of an elastic bandage round the limb on the proximal side. The degree of tightness of application is of considerable importance. One should remember that the object is to impede the return flow of the blood only, and that the pulse in the limb must not be affected. The skin of the part on the distal side of the limb should be of a uniform brilliant red colour, the limb should become warmer, and the patient should not experience any pain. The pain in the diseased part is at once relieved by the application of a bandage if the treatment is to do good and is being carried out properly. In acute cases this action is continued for 22 hours, and then there is an interval employed in reducing the œdema by elevating the part, and, if necessary, by massage. In parts of the body where an application of the bandage is not possible, the treatment may be carried out by reducing the atmospheric pressure on the part by suction. This method is particularly suitable to localised inflammations. In the treatment of abscesses only a small puncture is made, and when the bleeding has stopped, the suction is applied, and by this means the pus is withdrawn from the cavity. In such a case the suction may be continued for an hour, with intervals of three minutes every five. The usual dressing is then applied, and next day a similar procedure is repeated. If the puncture has closed, it should be picked open before the suction is reapplied. In the treatment of tubercular joints Bier recommends that the congestion be maintained only for an hour a day, as against the 22 hours recommended for acute infections. K.

Blood Changes Subsequent to Excision of Spleen.—Matthew and Miles report the result of a systematic examination of the blood of a patient whose spleen had been excised for traumatic rupture. The excised spleen was healthy, and consequently the case was a most favourable one for observations, and as observations were carried on over a period of two years and three months, both the immediate and remote blood changes were noted. They sum up their results as follows:—(1) After extirpation of the spleen, an enlargement of various groups of lymphatic glands occurs. The increase in size sets in early after the operation, is not of any great degree, is probably general, and is not permanent. (2) Corresponding to the lymphatic hyperplasia, there appears in the blood an absolute increase of lymphocytes. This increase persists in man for years after removal of the spleen. (3) A moderate eosinophilia appears soon after extirpation, and after persisting for some weeks again subsides. During the period of eosinophilia the blood plates are very numerous. (4) After recovery from the loss of blood, the red cells and hæmoglobin follow a normal course. (5) After excision of the spleen, individuals who recover suffer no inconvenience.
M.

Addison's Disease in Children.—Felbebaum and Fursthandler point out (*New York Med. Journal*, Aug. 10th, 1907) that Addison's disease is very rare in children. The number of reported cases is about equal in the two sexes, and the most usual recorded age is between 10 and 13 years. The typical form is characterised by its very prolonged course, accompanied by increasing weakness and gastric symptoms. In the rarer atypical forms the disease runs an acute course, and as the skin symptoms are often absent, the diagnosis is seldom made before the autopsy. Pigmentation, when present, is of a dusty bronze colour, most marked about the face, axillæ, knees, abdomen, and genitilia. The gastro-intestinal symptoms consist of loss of appetite and constipation, with occasionally diarrhœa. The pulse is small and feeble, and as a rule the temperature and urine are normal. The disease may last years, and may be characterised by occasional periods of intermission, death finally occurring with delirium and convulsions. The most common pathological change found is tuberculosis of the suprarenals, but cystic fibrous degeneration, and more rarely carcinomatous growths, have been recorded.
M.

The Value of Formamint in Septic Affections of the Oro-Pharynx.—M. de Santi has given an extensive trial to formamint in septic throat conditions, and now reports his opinion concerning its value in such cases (*Medical Magazine*, March, 1907). The drug is a combination of formic aldehyde and lactose, and when the latter becomes dissolved in the saliva, the formaldehyde is set free, and is able to exert a strong antiseptic action. De Santi has used it in the following conditions:—(1) Acute suppurative tonsillitis; (2) In the post-operative treatment of tonsillotomy and removal of adenoids; (3) Septic ulcerations of the pharynx; (4) In scarlet fever; (5) In acute septic infection of the pharynx and larynx; and reports very favourably of its value in all of them. He sums up its advantages as follows: (1) It is a proved antiseptic and bactericide, and is non-toxic in action; (2) It is far more efficient in its action than gargles or mouth washes; (3) Its pleasant taste makes it particularly suitable for children; and (4) Its portability is often a matter of considerable convenience. M.

The Excretion of Creatinin and Uric Acid in Some Diseases Involving the Muscles.—Spriggs writes an elaborate report of some investigations made into the excretion of creatinin and uric acid in various muscular diseases. He summarises his results as follows (*Quarterly Journal of Medicine*, Vol. I., No. 1, page 63):—(1) In two cases of primary muscular dystrophy the amount of creatinin in the urine was small, and the diminution was proportional to the muscular wasting; (2) In a case of myotonia congenita the excretion of creatinin was also low, in one of myasthenia gravis it was diminished in lesser degree, and in one of locomotor ataxia not at all; (3) In two cases of tetanus and one of spastic hemiplegia in a general paralytic there appeared to be only a slight increase; in a case of spastic paraplegia the excretion was normal; (4) In all these cases the excretion of uric acid deviated but little from the normal, being highest in the cases of tetanus and of spastic hemiplegia. From the above facts it is concluded: (*a*) that by far the greater part of the endogenous creatinin of the urine is derived from muscular tissue, but that it is a product of its internal structural metabolism, and not of its contraction; (*b*) the source of by far the greater part of the endogenous uric acid in the urine is to be looked for in the non-muscular tissues. M.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

PAUL.—The question of priority in the discovery of the infection of Malta fever is definitely settled by Colonel David Bruce, C.B., R.A.M.C., who states that the actual observation which led up to this discovery was made by Dr. T. Zammit, the Maltese member of the commission which was despatched by the Royal Society. Colonel Bruce's own words are:—"I went out to Malta as Chairman of the Commission in May, 1905, and discussed results of the work of those members of the Commission who remained in the island during the previous winter. I saw Dr. Zammit's notes as to two experiments on the effect of feeding goats on material containing *Micrococcus Melitensis*. I urged Dr. Zammit to continue his investigations, and he accordingly bought a small herd of goats. Before proceeding to repeat the feeding experiments on these new goats he examined their blood, as a matter of routine, and, much to his surprise, found that five out of six gave a Malta fever reaction. He then took specimens of the blood to Major Horrocks, another member of the Commission, and asked him to confirm his observations. This Horrocks did; and at once Dr. Zammit and he proceeded to examine, the former the blood and the latter the milk of the goats, for the *Micrococcus Melitensis*, with the result, as is well known, that this micro-organism is found in the blood, and excreted in the milk, to the extent of 10 per cent. of the goats of Malta."

AN UNLUCKY NAME.

DR. C. B. GRAVESTONE, a Chicago physician, who informed his creditors that he had been ruined by his name, had simply missed his vocation. He should have been a monumental mason. —*Star*.

Dr. H. S. T.—The "method of M. Boeri" is what is called Respiratory Auto-Massage of the Abdomen, and is prescribed in habitual constipation. The patient lies on his back (for preference) and makes deep inspirations and expirations, hollowing out the abdomen as much as possible during the latter. It is claimed, and reasonably so, that the intestinal contents are thus naturally acted upon.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 6TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. M. Collier: Clinique. (Surgical.) 5.15 p.m.: Lecture: Dr. C. R. Box: Bacterial Invasion of the Urinary Tract in Childhood.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

THURSDAY, NOVEMBER 7TH.

RONTGEN SOCIETY (20 Hanover Square, W.).—8.15 p.m.: Presidential Address:—Mr. W. Duddell: The Production of High Frequency Oscillations (with demonstrations).

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Clinical Cases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. T. G. Stewart: The Diagnosis of Cerebellar Tumours.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: The Solution of the Confusion between Pityriasis Rubra Pilaris and Lichen, and the Treatment of each.

HOSPITAL FOR SICK CHILDREN (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. Waugh: Appendicitis.

FRIDAY, NOVEMBER 8TH.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (20 Hanover Square, W.).—8.30 p.m.: Exhibition of Cases. Short Paper:—Dr. J. Fawcett: Pneumothorax treated by Aspiration under X-Rays. The Patients will be in attendance at 8 p.m.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. H. L. Eason: Clinique. (Eye.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Appointments.

BURKE, GERALD T., M.B., B.S.Lond., Senior House Physician at the Prince of Wales' General Hospital, Tottenham, N.

HARRIS, HENRY E., L.D.S., Dental Surgeon to the Royal National Orthopædic Hospital of London.

JAGO, W. J., M.R.C.S., L.R.C.P., Assistant House Surgeon to the Taunton and Somerset Hospital.

LEWTHWAITE, ALFRED, M.B.Lond., L.R.C.P.Lond., M.R.C.S., Resident Medical Officer at the Winsley Sanatorium.

REES, EDWARD DAVIES, L.R.C.P.Lond., M.R.C.S., L.S.A., Medical Officer of Health by the Newtown and Llanidloes Rural District (Montgomeryshire) Council.

STIDSTON, C. A., M.B., B.S.Lond., M.R.C.S.Eng., L.R.C.P.Lond., Resident Medical Officer and Secretary to the General Infirmary, Hertford, Herts.

Vacancies.

King Edward VII. Sanatorium, Midhurst, Sussex.—Pathologist. Salary, £250 per annum, with board, lodging, and attendance. Applications to the Hon. Secretary, 19 Devonshire Street, Portland Place, W.

West Riding Asylum, Wakefield.—Assistant Medical Officer. Salary, £150 per annum, with apartments, board, washing, and attendance. Applications to the Medical Director.

Leicestershire and Rutland Asylum.—Junior Medical Officer. Salary, £130 per annum, with board, lodging, and washing. Applications to W. J. Freer, Esq., 10 New Street, Leicester.

The North Riding Lunatic Asylum, Clifton, York.—Junior Assistant Medical Officer. Salary, £150 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Warrington Infirmary and Dispensary.—Senior House Surgeon. Salary, £120 per annum, with furnished residence and board. Applications to J. H. J. Hampson, Secretary.

Down District Lunatic Asylum, Downpatrick.—Junior Assistant Medical Officer. Salary, £130 per annum, with furnished apartments, board, washing, fuel, light, and attendance. Applications to the Resident Medical Superintendent. (See Advt.).

Castlebar District Lunatic Asylum.—Assistant Medical Officer. Salary, £100 per annum, together with annual allowances, including £50 in cash. Applications to Joseph T. Kelly, Clerk of Asylum. (See Advt.)

Births.

CARLYON.—On Nov. 1st, at Yeoville, Johannesburg, the wife of F. Harold Carlyon, M.D., C.M., of a daughter.

HUNTER.—On Oct. 29th, at Lynher House, High Street, Clapham, London, the wife of S. R. Hunter, M.D., M.Ch., of a son.

MICHELL.—On Oct. 26th, at 3, Trinity Street, Cambridge, the wife of Robert Williams Michell, M.D., F.R.C.S., of a son.

MISKIN.—On Oct. 31st, at Lonsdale House, Court Road. Eltham. the wife of Ernest Miskin, M.B.Lond., of a daughter, who survived his birth five hours.

Marriages.

FAIRLIE-CLARKE—LYELL.—On Oct. 31st, at St. Stephen's, Gloucester Road, London, Allan Johnston Fairlie Clarke, M.C., F.R.C.S., of Horsham, Sussex, youngest son of the late W. Fairlie-Clarke, M.D., F.R.C.S., to Violet, elder daughter of Captain F. H. Lyell, of Oakwood Hill, Surrey.

Deaths.

JOLL.—On Oct. 28th, at 1, Elm Grove Road, Ealing Common, Boyd Burnett Joll, M.B., M.R.C.S., formerly of Woolton, Liverpool, and Bedford Square, London.

PAUL.—On Nov. 1st, from a gun accident, Vining Paul, M.R.C.S., M.R.C.P., only son of the late J. M. Paul, of Upper Assam, India, and of Mrs. Paul, of Dovercourt, Essex.

SCOTT.—On Nov. 3rd, William John Scott, L.R.C.S., L.R.C.P.I., of Hurstpierpoint, Sussex, aged 46, second son of Richard Scott, solicitor, of Dublin.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, NOV. 13, 1907. No. 20

NOTES AND COMMENTS.

Juvenile Smoking.

THE anti-juvenile smokers are already on the alert for next session, for they succeeded last week in bearding the Under-Secretary at the Home Office and drawing from him official benedictions and platitudes. The fact of the matter is that the Home Secretary has his hands so full of pressing reforms and departmental Bills that he is not likely to give up much time to a petty matter of this kind. While of course no one approves of juvenile smokers, to hear the language on the subject used by some good folk, it might be imagined that the fate of the Empire depended on news- and errand-boys abjuring the "fag." It might not be objectionable in itself to make the retailing of tobacco to youths under sixteen an offence, especially as the cigarettes put up to catch youngsters are usually of the worst possible quality, but it would be nothing less than an outrage on common sense to make it a police court offence for lads to smoke in the streets. The amount of harm they would get from being treated by the law as prisoners, and from the associations of the police-court and the dock, would be infinitely greater than any physical deterioration they would be likely to suffer from puffing a little tobacco. So long as men smoke boys will imitate them, and we could only wish it was the worst habit they picked up from their elders.

The Triumph of the Midwife.

A CURIOUS gathering took place at Rotherham last week, namely, a combined tea-fight for midwives and prize-show for infants. The Mayor was in the chair, and Dr. Robinson, the Medical Officer of Health, addressed the company. In his speech, Dr. Robinson spoke of the waste of infant life that was going on in the country, and of the methods by which it might be averted. Foremost among these he placed the influence of educated midwives and the early notification of births. Figures were given showing that whereas the infant death-rate for England and Wales was 133 per 1,000, that of Rotherham was, on the average of the last ten years, 160 per 1,000. Since the introduction of early notification to Rotherham there had been 923 births, with 94 deaths, among infants whose mothers had been attended by midwives, against 910 births, with 177 deaths, among those not so attended. "He regarded this difference in favour of Rotherham midwives as extraordinary." So, indeed, do we, for the obvious inference is that infants do about twice as well when the mothers are attended by midwives as when they are attended by medical men. Prizes of sovereigns and shawls were then distributed to the midwives who had been most successful, and the mothers of the lustiest infants were made happy by similar presentations. While we have the greatest sympathy with all efforts made to check "the massacre of the innocents," we cannot think that figures that show so much are not capable of some other interpretation.

Tomato Putrifiée.

PEOPLE with a partiality for tomato purée may be interested to hear the opinion of the Medical Officer for the Port of Manchester on that delicacy. Two hundred and fifty-four tins of this stuff were recently seized by him, and the contents were found to be in a very revolting condition. We learn from the medical officer some of the tricks of trade with regard to tomato purée and other kindred goods. It is well known that when such articles of food putrify they give off gas which bulges out the side of the receptacle. Such tins are said to be "blown," and, being easily detected by their external appearance, are pounced on by the inspector. The owners are now as wily as their natural foe, and when tins are blown they puncture them, let out the gas, and solder up the hole, the chances being that the putrid stuff will be eaten before enough gas has been formed to bulge the tin again. Another trade dodge is what is known as the "sneaking" method, the removal of the lid of the tin to let out the gas, and the resoldering of it. Revelations of this kind are simply nauseating, and we feel at a loss for suitable comment. The only fit punishment we can think of is to sit the perpetrators of these tricks in a prison cell with no other food to eat but their own dainties, and the only effective one under modern humane conditions to advertise the names of the makers and their stuffs all over the kingdom, so that all may know what not to buy. Perhaps it was from dealings of this kind that tomatoes gained their legendary property of causing cancer.

London University Election.

THE election of a new member of the London University Senate by the Faculty of Medicine re-opens the controversies which were supposed to be settled by the recent election of Dr. Caley and Mr. Leonard Hill; it may be hoped that the electors will clearly realise the alternatives before them. Dr. Norman Moore and Mr. Wallis are asking for votes to help them oppose the scheme for a central institute for preliminary medical study, while Professor Starling appeals for votes in its favour. After all the crises London medical education has been through, no crisis, perhaps is more profound than that in which the small schools find themselves at present, and after all the bitter lessons of the past, it might be hoped that the present University graduates would be prepared to sink their own particular wishes in a desire to combine for the common good of the London student. At present this unfortunate individual is placed in the position of having the largest variety of clinical material in the world, and teachers whose names are often household words, and yet he is denied the routine advantage enjoyed for centuries by every Scotch lad who studies at a metropolitan or provincial university, namely, that of acquiring a university degree as the natural crown of his studies. All the reconstruction and re-fashionings of the London University will fail until the graduates who govern the University are prepared to make it a University *for* London. This policy they seem still opposed to, and people wonder why London is waning in popularity as a medical centre. As a matter of fact, for some of the famous, but smaller, schools the position is only just short of an *impasse.*

Medical Men and Sanitary Officials.

LAST week we commented on the state of sanitary administration at Manchester, and the insolent way in which the sanitary inspectors invaded the privacy of the homes of the poor and hectored them. We have since had the opportunity of reading an article in the *Manchester Evening Chronicle*, contributed by a medical man, in which the subject of medical notification is dealt with. The writer, in common with the members of the Manchester Medical Guild, protests strongly against the conduct of the inspectors, and he proceeds to discuss the general questions of notification as regards medical practitioners. He shows how distasteful to medical men it is for them to be turned into spies and informants as regards their patients, and he shows how the feelings of many medical men against notification of the ordinary infectious diseases having been overcome, the State has proceeded to extend the principle to voluntary notification of consumption, and now to compulsory notification of births. This method of getting from practitioners information obtained in the confidential relation of doctor and patient can only be justified on the ground of the greatest necessity, and it cannot but tend to erect certain barriers which should not exist between medical men and the patients, especially when the latter are poor. When, as in the case in Manchester, notification brings in its train a sanitary official, breathing out pains and penalties, it certainly is time to protest. The poor have their rights even when they are ill, and doctors, though wishing to co-operate in every way with health administration, do not wish to be made catspaws of a high-handed beaurocracy.

The "Kilkenny Cat" Position.

IN our last issue we published a letter from Miss Beatrice Kidd, in which, with a certain lack of gratitude, she said that the Hon. Stephen Coleridge, who has borne the burden of the "cause" in the heat of the day, "can hardly be called an anti-vivisectionist at all." We admit to having frequently been at a loss to define the exact views of that gentleman, but are we really to admit Saul to a seat among the prophets? That prospect does not seem likely to materialise in the immediate future, but Miss Kidd, having thus thrown Mr. Coleridge to the vivisecting wolves, proceeds to announce that, "on the side of the anti-vivisectionists we have a happy family party remaining." The happiness that animates this family party must, we fancy, be more the joy of combat than the domestic felicity of the fireside. For, apart from Mr. Coleridge's National Anti-vivisection Society, we have heard of the London Anti-vivisection Society, the British Union for the Abolition of Vivisection, the Parliamentary Union for the Suppression (or Abolition) of Vivisection, and the World's Union (or League) for the same, to say nothing of the Canine Defence League. We dare not trust our memory further, but we believe there are yet others. The worst of the "happy family" is that each member of it seems to want something different from the others, and if anyone approves of anything the rest show their zeal by promptly expressing discontent with their brother's conclusion. So far as we understand Miss Kidd's wishes, as expressed in her letter to us, they lie in the direction of abolishing medical inspection of experiments. Supposing the Commissioners recommended that this change should be brought about, and experimenters were able to work without the tutelage of the Home Office, how could one be sure that all the other societies and unions and Leagues would be satisfied too?

LEADING ARTICLES.

MEDICAL OFFICER'S REPORT TO THE LOCAL GOVERNMENT BOARD.

THE report of the Medical Officer to the Local Government Board is always a volume of the highest importance to the nation, and though nothing of a sensational nature is recorded in it this year, the standard of general interest is well maintained. As indicating the growing feeling in favour of sanitary matters all over the civilised world may be taken the fact that each year the international and imperial service rendered by the medical departments grows in size and importance. In 1905, for instance, the Government, on the invitation of France, appointed two delegates, Dr. Theodore Williams and Dr. Timbrell Bulstrode, to attend the International Congress on Tuberculosis, and though their report was technically presented to Parliament, probably nobody in Parliament looked at it; but on the other hand the medical department of the Local Government Board have abstracted from it all that is likely to be of help in the solution of tuberculosis problems in this country. Specially interesting are the efforts being made in France to catch individuals, especially children, in the "pre-tuberculous" stage, and to provide institutions in favourable spots and under favourable conditions for their reception. Again, the French "anti-tuberculous dispensaries" provide an experiment in medico-social work that should be carefully watched with a view to its imitation over here if necessary. These dispensaries act as a buffer between the sanatorium and other charitable agencies for the sick poor, and by meeting the wants of the latter in good time—even to the socialistic extent of supplying food and clothing when necessary—their supporters seek to ward off the conditions that predispose to tuberculous disease. From the less utilitarian standpoint, much interest also attaches to the views on "latent" tuberculosis expressed at the Congress, the idea being expressed that tubercle bacilli are frequently received into the tissues of children from one source of infection or another, and these lie dormant till some concatenation of circumstances in the altered condition of child-life render the subject vulnerable to their attack. Useful "imperial" service was rendered to the country by Dr. Theodore Thomson, who was sent to report on the advisability of establishing a sanitary station on the Persian Gulf in accordance with the proposals of the International Sanitary Convention of Paris in 1903. Dr. Thomson from his practical knowledge was able to point out that not only was there small danger of cholera and plague proceeding from the Persian Gulf, but that the sanitary station, if established, would not do much towards coping with it if it did arise. Moreover, the Gulf is so unhealthy and the expense of the station would be so large, that he advised that such an establishment would certainly be a mistake, and that an organisation should be prepared at Basra and Mohammerah to deal with the inland incursions of epidemic diseases.

In domestic affairs the department have been busy too. Freed from the necessity of looking after outbreaks of small-pox, the staff was employed in a more generous manner than is often possible in inspections and examinations. A rather disappointing account is given by Dr. Parsons of the £150 cottages on the Letchworth estate. From what we heard and read of these cottages, we were inclined to believe that there was no reason why a thoroughly satisfactory cottage should not be erected for that sum; but Dr. Parsons was not satisfied with a good many features they presented. We are inclined, however, to think that he was in a rather pessimistic frame of mind when he wrote his report, for one of the points he deplores about the houses is that the staircases of some are so winding that it would be "practically impossible to remove a full-sized coffin from the first floor by the staircase!" It might be hoped that in model cottages on a model estate, the necessity for such an event would be comparatively infrequent; at any rate if the melancholy need were to occur, special arrangements might be made, according as the wit or ingenuity of the undertaker suggested. An important report is made by Dr. Bruce Low on the vaccine establishments in Germany. The principle adopted in that country is to decentralise the manufacture of lymph; but as this entails great multiplication of machinery and buildings, and certainly the risk of lack of uniformity in results, we do not see that such a system is called for in this country. As a lesson in German systematisation and exactitude, however, the report is instructive.

One new and decided step forward has been taken by the Board, namely, that of setting up a special sub-department under Mr. Power's general guidance for the supervision of the administration of the Food and Drugs Act, Dr. Buchanan being appointed its provisional chief with the title of Inspector of Foods. An extensive enquiry has already been made by him into the danger of meat from tuberculous pigs in London; but unfortunately its length precludes its being reproduced in the medical officer's report. The usual inspections took place during the year under notice, some, especially the inspections of Basingstoke, Lincoln, and Fulbourne Asylum being of more than ordinary significance and importance. In appendix B we find reports from the researchers employed by the Board, Dr. Klein having three papers, Dr. Sydney Martin, Dr. John Wade, and Dr. Gordon one paper each, and Drs. Andrewes and Gordon a joint paper. It is not possible here to give any adequate idea of the scope of these contributions, but the most pretentious, undoubtedly, is the first one of Dr. Klein's, namely "On a New Plague Prophylactic." Let us hope it may prove so.

It is a matter for reflection that while the work of the medical departments of the Local Government Board is some of the most important and responsible in the country, and while, moreover, it is exceedingly well done, the amount of interest taken in it by the general public is practically nil. Perhaps after their vaccination experience of the lime-light of publicity, the department is not unduly cast-down after all.

A BLOW TO QUACKERY.

The issue of the recent article for libel brought against Mr. Labouchere, of *Truth*, registered a notable advance in the campaign against quackery. A verdict has been given and judgment returned in favour of the defendant. This result shows that it is still possible in the United Kingdom with impunity to call gross quackery by its proper name, and to expose the malpractices of charlatans who prey upon the public by professing to cure their maladies. The medical profession must admit their indebtedness to *Truth* in this matter, although at the same time we must repeat our contention that the journal in question admits to its columns quack advertisements of an obviously objectionable character. The fact that *Truth* accepts money for the insertion of advertisements of that class clearly weakens its position as a *censor morum*. Apart from this criticism, the editor of that incisive journal may be congratulated on the ending of the long-drawn-out and costly legal proceedings in the case of *Dakhyl v. Truth*. The plaintiff, who complained of being libelled, is a Doctor of Medicine of Paris. He came to England and assumed the direction of the notorious Drouet Institute for the treatment of deafness. The methods of that organisation have long been the subject of unsparing attack in the columns of *Truth*. They afford a scathing indictment of the laxity of British law in the protection of the public against the machinations of gross and unblushing quackery. The history of the Drouet Institute, properly unfolded, would be sufficient in itself to warrant the demand for new and stringent Medical Acts. Of what use is it to secure a proper education of qualified medical men and to label them so that they may be recognised by the community, if on the other hand any ignorant and unqualified person is permitted to advertise his claims as a curer of all and every ill that flesh is heir to by means of potions, charms, appliances, manipulations, and a host of special methods of every conceivable kind? The evil is immeasurably great, and it must one day be rooted out when society attains a higher general level of intelligence. Meanwhile, the nation pays the toll of its folly in the ruined health and the lives of the victims of patent medicine vendors and charlatans. As a practical outcome of the case under consideration, there has emerged a sort of judicial recognition of the definition of the word "quack," as one who professes to cure many diseases with one remedy. Mr. Justice Darling added the pronouncement that quackery might be practised by the holders of the highest medical qualifications. We imagine that the truism laid down by the learned judge has an application to professions other than that of medicine. At the same time he may be thanked by all honest citizens for having bestowed a good, hearty buffet upon that evil thing, quackery.

CURRENT TOPICS.

The Pollution of Rivers.

IN many ways the legislation of the United Kingdom, even in matters that are apparently of an urgent nature, is curiously slow and deliberate in its inception. Take the question of the pollution of rivers, about which there can hardly be at the present time any serious difference of opinion. The subject has been under the consideration of the Royal Commission on Sewage Disposal for the last nine years. It has been once again brought into prominence by a deputation from the British Science Guild which was last week received by Mr. John Burns at the Local Government Board. Sir William Ramsay pointed out that some permanent arrangements should be made to carry on certain aspects of the work of the Royal Commission on Sewage Disposal. It was true that a few local river boards existed, and were doing good work, but many more were wanted. A central body with authority to deal not only with the question of river pollution but with the whole question of water supply, was absolutely essential in order to map out catchment areas for districts and to keep them free from pollution. Unless something of the kind were done, twenty-five years hence it would be too late, and things would be in an extremely bad condition. Unless such a central board were created litigation could not be avoided in all these matters, and he instanced one case where £12,000 had been spent needlessly under present conditions. The cost of the present Royal Commission was roughly about £4,000 a year; but this expense would cease if a central board were created. The Commission, indeed, wanted to resign, but could not do so on account of the necessity of continuing the work. He did not think that the cost of the working of a central body, equipped properly for both chemical and biological work, would be greater than £6,000 or £7,000 a year. Mr. Burns received the deputation in a sympathetic speech, and expressed an opinion that the Local Government Board should be the central and joint authority in the matter of river pollution. The Bill he hoped to bring forward in the spring of next year would have to be warmly endorsed by public opinion in order to become a success.

A Model Sanitary Committee.

GRATITUDE for long and faithful medical public service is not often so conspicuously shown as by the townsfolk of Swansea in the case of their retiring borough and port Medical Officer of Health. After forty-two years in the service of the Corporation, Dr. Ebenezer Davies felt compelled to send in his resignation owing to his ever-increasing duties. Thereupon, an influential deputation from the Swansea Medical Association waited upon the Sanitary Committee of the town, and urged that Dr. Davies should be appointed Consulting Medical Officer, and that his successor be a well-trained bacteriologist in addition to the other necessary qualifications. The committee decided to advise the appointment of Dr. Davies as Consulting Medical Officer of Health at £100 per annum, and to appoint a successor at a salary of £700 or £800 a year. This graceful recognition must be gratifying to Dr. Davies, accompanied as it was with many expressions of esteem and respect. In introducing the deputation, Dr. Griffiths spoke of his work as always of an unostentatious character, and said that in the profession they looked upon him as a model of courtesy, consistency, conscientousness, and, he might say, honour. The relations between the Swansea Council and the Medical Officer of Health might well be taken as an example by many local authorities in other parts of the kingdom.

Plague in Glasgow.

A LOCAL outbreak of bubonic plague is announced in the Glasgow newspapers in a small district on the South Side. The nature of the disease has been confirmed by a medical officer specially despatched from the Local Government Board, Edinburgh. Patients have been promptly removed to the Belvedere Hospital, and "contacts" subjected to a fortnight's quarantine in the reception house. The invasion of a large town by plague is serious under any circumstances, but happily nowadays there is no need of a panic in our own comparatively well-ordered centres of population. Past experience, moreover, in this very locality is reassuring, for in 1900 plague appeared there, but was restricted to 36 cases, with 16 deaths. The following year it recurred in milder form. Its re-appearance in the same spot in 1907 renders it possible that the infection has persisted, and that it would have been wise to demolish the building where the disease formerly obtain a foothold.

Strait Jackets in Poor-Law Infirmaries.

FROM a medical point of view the use of the strait jacket, under any circumstances, is questionable, but most of all is it to be deprecated when left in the hands of laymen to administer. The Local Government Board appear to think the application of that antiquated appliance demands supervision, for they have intimated to the Hampstead Board of Guardians that an inquiry will be held with reference to the recent inquest on the body of an inmate of the workhouse. The peculiar circumstances of the case were that the man in question died in the observation ward of that institution after having been there seventeen hours, seven of which were spent in a strait jacket. From the newspaper report it is uncertain whether deceased was seen at all by a medical man, but it clearly intimates that he was placed in the jacket in the absence of medical orders. There is apparently no padded room in the workhouse, a fact that met with the Vice-Chairman's approval, if we may judge from the remark that such rooms were antiquated and undesirable. Of all things in the world we should have thought that that mild condemnation would have applied with a hundredfold force to the strait jacket. The whole question of, in our opinion, the Poor Law accommodation for refractory and delirious patients generally requires searching inquiry and stringent remedy in the interests of common humanity.

Birthday Honours.

ALL medical men will have found peculiar pleasure in seeing the name of Professor Clifford Allbutt in the Birthday Honours list. The honourable style of K.C.B. will sit on no worthier member of the profession; the only criticism we feel inclined to offer is that it has been long overdue. Dr. Allchin, another well-known physician and medical systematiser, has been made a knight, and Dr. Beatson, C.B., of Glasgow, long a devoted volunteer, has been promoted to the knighthood of his order. Both distinctions are well earned. Although not strictly medical, the knighthood of Mr. A. C. Scovell, who has been so long associated with the profession and with health administration in London, calls for special mention. It may be true that the world knows little of its greatest men ; it certainly is true that London is totally ignorant of the enormous debt it owes to Sir Augustin Scovell for his steady and fearless administration during the late small-pox outbreak. Two names are of special interest to Irishmen. Knighthoods have been conferred upon Mr. Robert Matheson, LL.D., who fills the important post of Registrar-General, and Dr. W. J. Thompson. Dr. Thompson, who is senior physician on the staff of Jervis Street Hospital, is one of the physicians to the Lord Lieutenant. He has been largely concerned in the working of the recent Tuberculosis Exhibition in Dublin. Mr. Robert Matheson is well known as a very able statistician. He, also, was deeply interested in the working of the anti-tuberculosis movement in Ireland, and contributed to the exhibition a large series of statistical tables relating to the same subject.

The Closing of the Tuberculosis Exhibition.

The closing of the Tuberculosis Exhibition in Dublin on Friday last was marked by lectures delivered in the theatre of the Royal Dublin Society by Sir Shirley Murphy and Dr. A. K. Chalmers on "The Control of Milk and Food Supplies and other Conditions affecting Tuberculosis," under the presidency of His Excellency the Lord Lieutenant. The subject of the lecture was well chosen, for up to the present Irish sanitary authorities have practically done nothing towards controlling the milk and food supplies with a view of preventing tuberculosis. It is, of course, too soon to judge of the effect of the exhibition as a whole. It is, however, safe to say that a degree of public interest in the question has been roused such as never would have existed before. It remains to be seen whether the public will insist, through the sanitary authorities, on making their opinions effective. We confess we have not much faith in the professions of the Local Government Board or of the various sanitary authorities. The former boasts of its energy and activity in pressing reforms on the local bodies, but this energy and activity began only a year or two ago, and little was heard of it until Lady Aberdeen brought the question to the front. The value placed by the Board on sanitary work may be judged by noting that the usual salary of a medical officer of health as sanctioned by them is £15 to £20 a year, and in some cases £5 a year. The local authorities, too, will always be obstructive until there is a strong public opinion to drive them on. If the exhibition has done any good, it is in the formation of this opinion.

Infantile Mortality in Durham.

The Archdeacon of Durham has made his triennial visitation at Durham notable by calling the attention of the clergy to the overcrowded population and the terrible infantile death-rate in the county. Speaking of the importance of the question of housing in Durham, he found that, while the population of Durham and Essex were practically the same, in Durham the percentage of overcrowding was 28.4 per cent., while in Essex it was 2.7 per cent. The deaths in Durham were 21,962, and in Essex 14,913. The rate of infant mortality in Durham was 156 per thousand births, and in Essex 115 per thousand, or three deaths in Durham to every two in Essex. They were better now in respect of overcrowding than they were twenty-five years ago, but they must be far better than they were that day before the clergy and laity could come to the conclusion that they had done their duty. Dr. Eustace Hill, Medical Officer of Health for the Durham County Council, pointed out that their county had the highest infantile mortality in England and Wales, with the exception of Glamorgan. One-third of the total number of deaths were infants under one year old, two-fifths of infants under two years, and nearly one-half under five years of age. Half of the total number of infants' deaths were preventable, and the total number of avoidable infant deaths were 100,000 yearly. In this matter the Archdeacon has set a worthy example to his fellow Churchmen, who will find in social reforms a field of altruistic labour worthy of the highest ideals and traditions of Christianity.

PERSONAL.

The King has bestowed another mark of his favour upon Sir Frederick Treves in granting him as a residence Thatched House Lodge, Richmond Park, a charming house standing in three or four acres of beautiful grounds.

The County Council of Bedford have appointed Dr. G. F. McCleary, Medical Officer of Health for Hampstead, as Medical Officer for Bedfordshire.

Professor Clifford Allbutt has been appointed a K.C.B. (Civil Division).

Dr. W. H. Allchin and Dr. W. T. Thompson have been made Knights Bachelor.

Lieut.-Colonel and Hon. Colonel G. T. Beatson, C.B., R.A.M.C. (Volunteers), of Glasgow, has been promoted to be K.C.B.

Dr. R. M. Coulter, Deputy Postmaster-General of Canada, has been appointed C.M.G.

Dr. Preston King has been elected to the Town Council at Bath; Dr. H. A. Latimer at Newport; and Mr. Paul Swain at Plymouth.

There is a vacancy for a medical member on the Senate of the University of London, caused by the resignation of Dr. Lauriston E. Shaw.

Dr. James Pearson, J.P., has been elected Mayor of Bootle for the present year.

Mr. W. H. Power, C.B., F.R.S., medical officer to the Local Government Board, has been awarded the Buchanan medal of the Royal Society.

Dr. Ronnaux, surgeon of the St. Julian Hospital at Cambrai, has contracted tetanus from an operation, and though his arm has been amputated his life is despaired of.

Dr. Louis C. Parkes, Medical Officer of Health for Chelsea, will introduce a discussion at the Royal Sanitary Institute to-morrow (Thursday) night on the "Smoke Problem Abatement Society."

The Public Health Committee of the Corporation of Dublin has presented a beautifully illuminated address to Sir Charles Cameron, C.B., Medical Officer of Health for Dublin City, in which the Committee congratulates him on the success of his efforts to improve the state of public health in Dublin.

A CLINICAL LECTURE
ON
DEFORMITIES OF THE FOOT ASSOCIATED WITH ABDUCTION.

By EDRED M. CORNER, B.Sc.Lond., M.C.Cantab, F.R.C.S.,

Surgeon in Charge of Out-Patients, St. Thomas's Hospital; Senior Assistant-Surgeon, Hospital for Sick Children.

GENTLEMEN,—To-day I want to talk about the reverse of what we were speaking about on Monday. I then showed you a number of slides illustrative of the deformities associated with the adducted position, which the foot assumes during activity. This afternoon I wish to show you a number of slides setting out the positions and deformities of the abducted foot, which position of abduction the foot assumes during rest. In this slide the arch of the foot is not much marked, although it is not entirely obliterated. And it is very useful in practice if you can remember that the foot can become abducted, and therefore present all the symptoms which you naturally associate with flat foot, and yet have a slight arch. The next slide shows the position of the bones of the foot in abduction or rest. The toes are turned outwards opposite the mid-tarsal joint. In contrast with that, I show you a slide of a foot in adduction or activity. In activity there is a raised heel and increased arch, the person standing on the toes. In the movement of adduction the toes are turned inwards and the movement has taken place about the mid-tarsal joint.

I now want to show you how this abducted position of the foot can be recognised in early life. Inactive, young, or weakly people turn their toes out; as people grow older their tendency is to assume the abducted position. This is caricatured in the shuffling gait of the aged. People who turn their toes out and have abducted feet do not lift their feet well from the ground, so that their gait is never as clean and neat as that of people having adducted feet. In people who maintain their feet naturally in the abducted position one finds long narrow feet, with smooth uppers of their boots. In the abducted foot the heel of the boot is always worn on the outer side. I remember one case where that point was brought prettily into the Law Courts. A man had sustained a Potts' fracture of his leg, and the result of the reduction of the deformity was to leave his foot in the flat or abducted position, a position which I fear is fairly common after Potts' fracture of any severity. The employer's insurance company, which was dealing with this man, refused compensation, and the case came to the Courts. A number of surgeons from the West End went to give evidence. The first surgeon-witness, an important and well-known man, had this pointed out to him; the patient's boot was produced to him. He explained very carefully to the judge and jury that the man now, as the result of the accident, was walking on the inside of his foot. The counsel on the other side produced the boot and asked this very important surgeon why it was, if the man walked on the inner side of his foot, he wore away the outer side of the heel!

The next slide shows the sole of an abducted foot; and you will notice a callosity occurs beneath the third toe. Sometimes instead of one callosity you find there are two. The callosity in the active foot is partly under the ball of the big toe. Abduction is the position of the slow, the heavy, the inert. It is associated with a number of deformities, which we can classify as (*a*) those taking place at the ankle joint, like talipes calcaneus; (*b*) those taking place at the mid-tarsal joint; and (*c*) those taking place at the metatarso-phalangeal joint. We have not time, nor would it be profitable, to go into all these deformities to any extent. We will speak of only a few.

First, there are deformities of the ankle joint. There may be a combination of *talipes calcaneus, valgus, and flat foot.* These factors are always present, and are quite inseparable in the acquired deformity. The acquisition of this deformity is largely dependent on the integrity of one muscle, namely, the tibialis posticus. That is a muscle in the calf of the leg whose function is the raising of the arch of the foot. Whenever the foot is active, as in springing and jumping, the heel is raised from the ground and the arch of the foot is increased, so that nobody can have an active foot unless the tibialis posticus is well developed. The peronei muscles are its great antagonists, and if those muscles have the mechanical advantage, the foot will flatten, and will enter into a position which you might call talipes equino-valgus, but which I prefer to call *pes abductus.*

Everybody is conversant with the ordinary condition known as flat foot, but I would impress upon you that people may come complaining of all the symptoms of flat foot, yet may not have a flat foot. *It is not flatness of the foot which leads to the complaint, but the abducted position of the foot.* There is a point here in regard to the treatment. The time-honoured treatment of cases of flat foot has been to teach them exercises; but if you have had the opportunity of watching a person who has been having his flat foot treated by exercises, you will have found that the exercises have certainly made him better, but they have not given an arch to the instep; the foot remains flat. The teaching of exercises has only recently come from Sweden into the hands of the more intelligent instructors. In connection with these exercises I would remind you that we are really considering only two muscles: the tibialis posticus and the peronei group. The first of these raises the arch of the foot, so that it is absolutely necessary to every person whose foot is to assume the position of activity. The peronei flatten the arch. The function of the peronei in ordinary people is to evert the foot. But if the foot is already flat it is already turned out, so the peronei cease to be everters of the foot and become flexors, like the other calf muscles. So if people whose feet are flat and therefore already abducted are taught tip-toe exercises in the ordinary way, those exercises will strengthen the tibialis posticus, and at the same time strengthen the antagonising peronei. But the exercise, while strengthening the muscle which raises the arch, also strengthens the muscle which flattens is, so the arch remains flat, although the patient is better. In this connection I would mention another condition which is associated with the abducted position of the foot, namely, ingrowing ankle. Unfortunately, these people are often put into strong boots with stiff uppers. That is a great mistake, comparable to putting a stiff jacket on to a case of lateral curvature of the spine, instead of by exercises and other measures improving the musculature of the back. In ingrowing ankles also the musculature must be improved, especially the tibialis posticus. This should not be done as the superannuated soldier teaches boys, with the toes turned out; but with them pointing straight forward, or even turned a little inwards.

The next deformity associated with the resting position of the foot occurs at the metatarso-phalangeal joint; is that very common deformity *hallux valgus.*

(*a*) Delivered at the Medical Graduates' College and Polyclinic, London. 1907.

Here I show you a slide of hallux varus, which is associated with the active position of the foot. Hallux valgus is usually attributed to badly-shaped boots; but this is not always so. If you examine such a foot whilst inside the boot you will often find quite an interval between the toe and the inner portion of the boot. Hallux valgus is a part of the abducted position of the foot, and as a result of that, the inner side of the head of the first metatarsal is pressed against the boot upper; and whenever a bony point is pressed or rubbed against a firm thing like the upper of a boot, it develops a bony boss on that surface, and so the toe will be pushed into a position of hallux valgus. The operation usually done consists in removing this bony boss, and passing a tenotome through to divide the contracted ligament. (*a*) It is common for people to forget to divide that ligament, but if that is not divided, the toe will not go into place. After doing that operation, warn the patient that the toe will not stay in the position in which it has been placed, but with the removal of the piece of bone and bursa it will probably be painless. In every case of hallux valgus a certain amount of attention should always be given to the boots worn. The usual idea is that these people should wear broad-toed ugly-looking boots; but that is quite unnecessary. As a sort of rough-and-ready test you can estimate whether a boot is right or not by drawing a line parallel with the inner margin of the boot. If it is a well-made boot this line will pass through the middle of the heel.

Now I want to say a word about *hallux rigidus*, particularly in association with the inactive or abducted position of the foot. This is the form usually described in the text books and shown in the out-patient room. In this condition, as you know, the big toe stands out, and is stiff and painful. Hallux rigidus, as ordinarily described, can be bent towards the sole of the foot, but not in the contrary direction. That is the distinction between hallux rigidus associated with the active as compared with that of the inactive foot. The proximal phalanx of the big toe moves round the head of the metatarsal bone in an arc of a circle, the radius of which is the lateral ligament of the joint. If on the dorsum of the head of the metatarsal a bony boss forms, it will slowly push the phalanx, so that the toe gets bent upwards. In the inactive foot, pressure is not borne there. The callosities of the sole of the abducted foot are under the third toe, not under the big toe. But in the inactive foot it is the upper part of the head of this metatarsal which is driven against the boot upper. As the upper part of the bone enlarges, the ligament will be tight, and the toe will be more and more bent in towards the sole of the foot. This slide shows hallux rigidus not as ordinarily described; the bony boss is on the lower surface of the metatarsal, not the upper; and as the deformity grows, the phalanx will become dorsally flexed, so that it curls up backwards. This is hallux rigidus of the active position of the foot. As the bony boss on the upper part of the metatarsal continues to grow, and the big toe becomes more and more flexed into the sole of the foot, there arises the condition described as hallux flexus. If it requires any treatment it is almost invariably amputation at that joint. The next slide shows hallux extensus, and it is associated with the active position of the foot. The bony boss is developed on the under-surface, so leading to the dorsiflexion or extension of the toe. Such a condition will lead to a transverse crease developing in the upper of the boot. The first line of treatment of this is by means of exercises, which may be combined with passive manipulation of the toe. In teaching such exercises, as tip-toe exercises in hallux rigidus, it is well that they should be begun with the toes turned outwards; then the toes should, every day or every two or three days, be turned a little more in, until finally, if the exercises are going to cure it, the patient should be able to perform them with the toes turned in. With regard to operative treatment in such a case, when it is associated with an inactive foot, with the bony boss on the head of the metatarsal bone at the top, you need have no scruple in taking away the head of the first metatarsal. That seems a severe piece of advice, when it is remembered that the great stress falls on the first metatarsal; but that is untrue of the inactive or abducted foot, and it is in this that the ordinary hallux rigidus of the textbooks occurs; and in those cases the under-surface of the head of the metatarsal bears no pressure during walking, therefore its loss will not be much felt by the patient. The next slide shows that the bony boss on the head of the first phalanx formed at the lower part, and a bursa, and then a corn, and the distal phalanx is extended or flexed towards the dorsum of the foot. In that case you find a corn under the head of the proximal phalanx. It is not uncommon to see in the out-patient room a corn not under the ball of the big toe, but under that toe more distally. When that is the case one can be certain that the foot is habitually in the inactive position. For this deformity I suggest the name *digitus extensus*.

This slide shows hallux valgus, and in that the valgus takes place partly in the metatarso-phalangeal joint, and partly in the interphalangeal joint. In the next slide the phalanx is affected at the interphalangeal joint solely. So it is a case of *digitus valgus* of the great toe.

The next slide shows ordinary hammer toe, and the deformity there is the same as that which I showed under the name *digitus flexus* of the great toe. The general operative treatment consists in making a lateral incision through the skin, dividing the lateral ligament at the interphalangeal joint, and removing the head of this proximal phalanx. If it ever was necessary, as it very uncommonly is, to operate on a case of digitus flexus of the great toe, then a similar lateral incision is made, and the head of the proximal phalanx will be removed.

And now I want to say a word about ingrowing toe-nail. It is a very common condition, and I want to point out the many reasons why it is commonly associated with the abduction or the inactive position of the foot. The ingrowing toe-nail, especially early cases, can be cured by ordinary local cleanly treatment, and the treatment for the abducted position of the foot, by which I mean tip-toe exercises, with the toes turned out, but with the foot directed straight forward. In very few of these cases is it necessary to proceed to operation, but where that is required, these slides show what should be done. Half the nail and the matrix are removed, and the wound sewn up (*a*).

It had been my intention also to speak about deformities of the leg and elsewhere which one finds associated with the abducted position of the foot.

People whose feet are in the inactive position, if they fall on their feet, are far more liable to injure them, and to break a bone, particularly the second or third metatarsals, than are people with adducted feet. In these cases one is apt to find pain and tenderness persisting for a long time about the base of the third metatarsal bone. It is very difficult to know why this pain persists; one is apt to think some more severe injury has been overlooked. Skiagrams do not help us much in this matter, because they do not show us distinctly the parts in the region of the base of the third metatarsal. In an abducted foot, it is difficult to state whether the lesion about the base of the third metatarsal bone is fracture, or a partial dislocation, or an injury only, of the soft parts, which is called a sprain. If one starts massage and exercises as soon as it can be done, one knows that that injury will get well in two or three months. Still, the patient usually suffers from some disability all his life. If he be a labouring man, he is not able to stand so long as he formerly could, or he is not able to go up a ladder as well. Thus there is something taken off his wage-earning capacity. These cases should be borne in mind and understood, because they often figure in legal actions against employers.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by R. L. Swan, F.R.C.S.I., Surgeon to Dr. Steevens' Hospital and to the Orthopædic Hospital, Dublin. Subject: "A Reference to Some Tubercular Diseases of the Knee-Joint, and to the Treatment of the Synovial Cavities."*

ORIGINAL PAPERS.

DEATH FROM HÆMORRHAGE FROM A MEDICO-LEGAL POINT OF VIEW.

PART II.

BY PROFESSOR HENDRICK, M.D.,
Of Hamburg.

(Specially reported by our German Correspondent.)

Continued from page 494.

II.—DEATH FROM HÆMORRHAGE IN CONSEQUENCE OF SOLUTION OF CONTINUITY OF THE GREAT BLOOD VESSELS.

Death from solution of continuity of the great blood vessels, aorta, innominate artery, pulmonary artery, inferior and superior vena cava, is not frequent, as they lie in a position specially protected by the sternum.

When they are wounded, death, as a rule, follows very quickly—more quickly than when the heart is wounded (as Richter showed in his experiments on animals), as the blood finds less resistance in the adjoining tissues, and in consequence of the impossibility of assistance it flows uninterruptedly.

The bleeding takes place into the mediastinum, and after bursting into the pleura, into the pleural cavity, or when the abdominal aorta is injured, into the abdominal cavity. By compression of the lungs, as shown by Richter's experiments on rabbits, the bleeding is somewhat checked, but it has never been observed that this has ever had any influence on the rapidity of the course. Pneumothorax may be associated with the hæmatothorax that is set up. As regards the causes, besides the traumatic, spontaneous rupture may take place, or rupture from very slight force, especially in the case of the aorta (rupture of the aorta). These are caused by morbid changes of the arterial walls, arteriosclerosis, fatty degeneration, endarteritis, aneurysm, the extension of ulcerative processes from adjoining parts (cancer of the œsophagus, caries of the vertebræ, foreign bodies that have stuck fast in the œsophagus).

If the rupture affects the whole three coats of the vessel, the bleeding is more rapid. The favourite place for rupture is just over its commencement. Generally the rupture is transverse. If only the intima and media are affected, a dissecting aneurysm may form, and the bleeding may be interrupted by it, but only for a short time generally—a few hours to a few days. The adventitia at last yields to the pressure of blood, and death from hæmorrhage takes place. If the vessels are healthy, only extraordinary violence can cause them to rupture. A case described by Langenbeck of rupture of the aorta without disease of the vessel is an exception, where a perfectly healthy person at a trial in court suddenly collapsed from rupture of the aorta (quoted from Drenckheim). Proof or a causal relationship between rupture of an aneurysm of the aorta and an earlier violence that has been followed by an aneurysm is extremely difficult to establish. Thus Pantzer describes a case where the question for decision was: Had the aneurysm that caused the death any causal relationship with an accident that happened seven years before? The three opinions that were given by three different experts did not agree as to the cause. As most aneurysms develop without any demonstrable cause, an aneurysm that leads to fatal hæmorrhage may at most, with some degree of probability, but not sufficient for a judicial decision, be traced back to a former injury.

Bleeding to death from solution of continuity of the sub-clavian vessels is, according to Israel, extremely rare, and this is attributable to their protected position. It is distinguished from that before described, in so far that it may be either internal or external, and assistance may possibly be rendered. The internal hæmorrhage runs the same course as that of the great cardiac vessels before described. When it is external its course may be retarded by the blood making its way under the muscles, and the formation of a clot. Death takes place from the hæmorrhage alone, or associated with air embolism with its resulting suffocation (complicated death from hæmorrhage). The course of the bleeding may be interrupted by the formation of a spurious or varicose aneurysm, that ruptures suddenly and leads to death. If, after professional assistance has been rendered, death takes place from late hæmorrhage, it is, according to Maschka, the business of the medico-legal expert to decide how far the injury itself caused the death, and to mark how far improper behaviour on the part of the wounded man himself, how far the professional treatment or any accidental wound contributed to the late onset of hæmorrhage. Here it may be a question of neglect on the part of the surgeon; but as Sachs specially notes, it is to be borne in mind that, in spite of the omission of a surgical operation, which must have been a considerable one, the patient would not be saved. Cases of this kind are given by Seydel (Kasuist. Mitteilungen aus der forens. Praxis, Vierteljahrsch. f. gerichtl. Med., Bd. XLIII.), and by Nussbaum (Friedrich s. Blätter f. gerichtl. Med., 1876, S. 146).

Bleeding to death plays a great *rôle*, from a medico-legal point of view, in the frequently occurring deaths from the throat being cut in cases of murder and suicide. If the carotid is wounded, death takes place in a short time, as the blood can flow outwardly without check. If, as happens in most cases, the trachea is opened, the blood flows from the superficial vessels (the external jugular and the superior thyroid artery and their branches), as well as from the deeper ones, into the respiratory passages, and suffocation ensues before the patient bleeds to death. The great veins of the neck being opened also, air may enter, and death be caused by air embolism. The case is therefore one of complicated death from hæmorrhage from blocking of the air passages or from air embolism. The quantity of blood which continues pouring out from the body until death cannot be measured; in any case of death with this complication a much smaller loss of blood leads to death than in ordinary cases. The decision of the question as to the deed, whether murder or suicide, frequently presents difficulties. The following may be taken as general criteria: The suicide stabs from above on the left downwards towards the right or from above on the right downwards to the left, according as he is right or left-handed. Often from repeating the stabs, or from the skin falling into folds from involuntarily bending his head, he will show several incised wounds; whilst in murder, often committed whilst the victim is asleep, there is more generally one deep and more horizontal wound. The suicide will sometimes show secondary incisions on other parts of the body from unsuccessful attempts; he will have the weapon in his hand, and this will be bloody. On closer consideration of these criteria, we must concede that Puppe is right when he says:—"The differential diagnosis in cases of death from cut throat between murder and suicide offers a remarkable uncertainty, whatever the circumstances may be. A series of distinguishing signs are usually present in murder cases, but there is not one that has not been observed in suicide cases also, and *vice versâ*."

Bleeding to death from wounds of the large vessels of the lower extremities occurs the most frequently of any of the kinds hitherto described; it is especially the subject of medico-legal inquiry, as suicide from wounds of the arteries. It is distinguished from death from hæmorrhage from injury of the subclavian artery in being more accessible to assistance either by the injured party himself or by others; its course may therefore be interrupted, but if the aid is not speedily on the spot, the end comes quickly. Moreover, in spite of professional assistance, death often takes place from secondary hæmorrhage.

Bleeding to death may also occur from injury of superficial veins. Thus Caspar-Liman mention a case

(Kasuistik, No. 128), in which a person rising from a broken night commode injured the saphena vein and bled to death. Schlag also reports a case of a person who bled to death from an opening in the saphena vein of the right leg, which had been made with the intention of committing suicide. Bleeding to death was rendered possible here by the vein being varicose and adherent to the periosteum.

Leonpacher (Aerztl. Sachverst.-Zeit., 1898, No. 5, S. 99) cites a further case of the kind, where a woman in a railway carriage bled to death in 13 minutes from a vein that had burst without knowing herself that she was bleeding.

Bleeding to death may also occur from smaller vessels than those mentioned, but unfavourable conditions are usually necessary, especially a morbidly diminished power of coagulation of the blood (hæmophilia). In the latter cases even a slight injury may cause fatal hæmorrhage (extraction of teeth, epistaxis, etc.).

Fatal hæmorrhage may take place from parenchymatous bleeding from injuries of the corpora cavernosa, the tongue, and the spongy bones. Injuries of the corpora cavernosa occur principally from attempted rapes and injuries of the female genital organs which will be described later. In fatal hæmorrhages from the tongue, the fatal termination is mostly complicated by the blood finding its way into the lungs and causing suffocation, but the fatal result may follow from external hæmorrhage only (Colley) (32).

Fatal hæmorrhage from parenchymatous bleeding is almost always internal. In diseased organs it may be spontaneous or from only slight violence, but in healthy organs only from the effects of considerable force. The following have been observed: being run over, falls from a height, crushing between fixed or moving objects, a blow, a push, or a fall. The diagnosis can only be determined on opening the body, especially in the not rare cases in which the body shows no external marks of violence. For determining the diagnosis—whether of spontaneous or traumatic origin—the situation and direction of the opening are of value; if spontaneous it will be found at the spot where experience teaches the disease is by preference localised, whilst in traumatic ruptures certain physical laws will be followed as to size, consistency, position (whether protected, etc.), the form of consolidation, the condition of the hollow viscera as to fulness, and the form of rupture. In the meantime the points of predilection for rupture of organs as determined by experiment are more important from a scientific than from a practical point of view (see Geill) (35).

More in detail to be discussed are fatal hæmorrhages from ruptures of the brain, liver, lungs, spleen, kidneys, pancreas, stomach, intestines and bladder. Ruptures of the heart and aorta have already been treated of. Ruptures of the female genital organs will be treated by themselves.

Fatal hæmorrhage from bleeding into the cranial cavities from the venous blood vessels, the meningeal artery and its branches, the basilar artery and its ramifications (intra-cranial hæmorrhage), may appear under very varied aspects from a medico-legal point of view. The simplest cases to determine are those in which there has been fracture of the skull, laceration of vessels, cerebral hæmorrhage, or rupture of the brain, fracture of the skull being a certain sign of traumatism. Death takes place from paralysis from blood pressure, and generally not immediately after the injury, but after a certain time—hours, sometimes even days—have elapsed, during which the signs of pressure gradually increase; or also directly from breaking up of brain substance, in which latter cases there are transitions in the mode of death from crushing of important organs. It is important here to observe that signs of external violence may be altogether absent, and that the part injured does not always correspond to the part where the violence has fallen, but frequently lies quite opposite to it (contre coup). Those cases are more difficult to determine, but also more rare, in which vessels are torn or even the brain lacerated without any fracture of the skull being present. Zaajer describes such a case (36), where a woman aged 38 died from laceration of the brain without any fracture of the skull, probably after being abused by her husband; the man, however, in the absence of legal proof, got off. Defraneschi (38) (Aerz. Sachverst. Ztg., 1902, No. 7), mentions a case where a countryman received a blow on the head. The next day he became unconscious and died in 24 hours. The autopsy showed laceration of the middle cerebral artery and effusion of blood without any fracture of the skull.

The mechanism of these injuries, according to the experiments of Bruns, Baum, Messers and Treub (7), is as follows: The elastic skull is compressed by the violence by which the cerebral fluid is forced back into the cavity of the spinal cord; after the cessation of the violence the skull springs back quickly, the fluid cannot move so quickly, and a negative pressure arises within the skull, whence the rupture. The place of rupture may be in any part.

Those cases are most difficult to determine in which there is disease of the walls of the vessels—arterio-sclerosis, small miliary aneurysms (Hofmann), vascular internal pachymeningitis, which may have caused spontaneous rupture, but in which there has been a possibility of a traumatic origin.

These cases are frequently the subject of legal proceedings when property is in question (Schilling) (37), where violence may be asserted when there has been none, or of so trivial a nature (a box on the ear) that for the first moment one doubts the deadly effect. The number of possible origins in these cases is great. A box on the ear may be fatal when the skull is thin, a blow of the fist, if there is an aneurysm, a fall from slipping may be fatal because the man is a drinker with arterio-sclerosis. The decision will be still more difficult when death does not follow the suspected incriminating event immediately, but later, as the following example from a collection of medico-legal opinions from Vienna shows: A woman was struck on the head with the fist, possibly also with a closed knife; she fell down, and remained several hours on the ground, got up again and walked away; possibly also she again received blows on the head. The morning after she was found dead in bed. Post-mortem examination: superficies of the brain covered with blood. The question was: did she die from violence, a blow, a fall, a push, or was she thrown, or was it in consequence of lying on the cold ground in a drunken condition, or after the excitement of a fit of rage? In a similar case, where a blow on the head, brandy, and struggling had caused extradural hæmorrhage and bleeding between the cerebral hemispheres, a ruling opinion was given to the effect that the brandy and the struggle were secondary causes. Another case in which apoplexy had taken place in consequence of leucæmia, shows how easily an inconspicuous trauma may be taken as the cause of the hæmorrhage in such cases.

The differential diagnosis between spontaneous and traumatic hæmorrhage may be determined according to the following criteria (Schilling) (37):—

(1) Spontaneous hæmorrhages are mostly central, and spread from within outwards, and have a known seat which, according to Andral (quoted in Schilling), was out of 386 cases 61 times the corpora striata, 35 times the optic thalamus, 27 times the centrum ovale, and the ganglia 202 times. They mostly proceed from the branches of the artery of the fissure of Sylvius, and pathological changes of the vascular system are found in other parts.

(2) In traumatic hæmorrhages without fracture of the skull there are dural, sub-dural, or arachnoideal hæmorrhages in one large or several small collections. If central extravasations are present, they are always accompanied by bleeding from the meninges. V. Bergmann decided in a case where a drunken man was struck to the ground, that the absence of meningeal extravasations with a central one in the interior was in favour of a spontaneous origin.

Fatal rupture of the liver always takes place when the lesion is of a certain extent. Death after the injury may not be rapid, as might be expected where the blood has free exit into the peritoneal cavity. In a case observed in v. Nussbaum's klinik (quoted from Drenckhahn) (26), a man who had been crushed between wagons, and after this injury walked to the hospital six hours afterwards, died from a large rent in the right lobe of his liver. According to Puppe (26), rents are distinguished according to their situation, in the convexity, at the base, and sub-capsular. The liver tears from contusions most readily of all the organs of the body in consequence of its size and its method of fixation, its dependence in firm ligaments, The blunt injuries that cause the liver to give way are, according to their frequency, the following (Heinzelmann) (13): the most frequent is being run over; next a push; thirdly, falls from a great height, from a horse, a wagon, and such contusions. It is indubitable that pathological processes make the liver more likely to tear under the influence of slight degrees of violence (Geill) (35). In a case mentioned by Chiari (11), a carcinomatous liver ruptured from turning in bed. Heinzelmann (9) reports a case of rupture of the liver that could have arisen from turning in bed or from a forced inspiration. In two other cases one was from a fall on the right side (tuberculous omentum), the other from a fall on the ice (tuberculous diathesis). Fischer (11) states that ruptures of the liver are seen from slight blows over echinococcus cysts; Taylor (11) is of opinion that a liver with fatty degeneration may rupture from contraction of the abdominal muscles. Lidell, Strassmann, and Hofmann express themselves to the same effect. According to the Handbuch der Chirurgie, by v. Bergmann, tuberculosis, syphilis, and amyloid predispose to ruptures. Experiments made on dead livers with regard to friability or firmness (Caspar-Liman, Ogston, Strassmann) have not led to any uniform results of practical value. In the same way no special direction of rupture after contusions, as compared with spontaneous rupture, has been determined. It can perhaps only be said that amongst the kinds of rupture the sagittal in the middle part preponderate.

Ruptures of the lungs come in the second line as regards frequency of occurrence. Fatal hæmorrhage from rupture of the lungs takes place from every moderately severe injury of them. It is mostly complicated by bleeding into the opened air passages and consequent suffocation, which when the force is great follows immediately with formation of hæmato or hæmato-pneumothorax and subsequent compression of the lungs. The lungs being so well protected against injury by the chest walls, for rupture to take place the larynx must be closed through fear at the moment of compression, when the lungs burst like a bladder filled with air, naturally at some locus minoris resistentiæ, caused by disease. As to the direction of the rent morbid conditions of the lungs have less influence than pleuritic adhesions (Altmann) (41). The principal line of rupture is longitudinal along the posterior inner margin of the lungs, the next hilus rupture, rupture between the lobes. It is also to be noted that ruptures may affect the inner parts of the lungs only, without being visible externally, and these may arise from purely internal causes, so that from the condition found there may be nothing to indicate external violence (Caspar-Liman).

In injuries and ruptures of the spleen, which in regard to frequency occupy the third place, the hæmorrhage is generally fatal, either immediately or from an intervening cause (peritonitis), as is shown in statistics collected by Heidenhain (42). From statistics by Edler (quoted from Handbuch by v. Bergmann) of 44 ruptures, 42 were fatal, 39 from hæmorrhage, 3 from peritonitis. Death does not always take place rapidly, but in a case of Schwing's, for example, half an hour after the rupture in a pregnant woman, in a case reported by Tomkins (*Lancet*, Jan. 4th, 1881), three weeks after. Ruptures of the healthy spleen are very rare on account of its protracted situation, provided the force acting on the abdomen is not actually a crushing one. Sometimes they occur in new-born infants from manipulations during birth. The pathological conditions that cause the spleen to give way easily are infarctions, acute swellings from infective diseases, particularly typhoid, chronic enlargements of it from venous stasis, disease of the heart, cirrhosis of the liver, and especially malaria (important in malaria districts). Playfair (7), in the course of two and a half years in the East Indies, saw more than 20 cases of rupture of the spleen; he states that in those parts one-third of the whole population suffer from enlargement of the spleen. As causes that bring about rupture of the unhealthy spleen, violent muscular contractions of the abdominal muscles and of the diaphragm are mentioned (v. Bergmann's Handbuch der Chirurgie), for example, violent sneezing (Silberstein), vomiting (Kering). Even palpation of a splenic tumour in a cachectic individual may cause rupture of it (Colin). In order to explain the mechanism of rupture of the spleen, one must look upon it as a hollow organ filled with fluid and suspended by ligaments (Geill). Rupture from violence is usually transverse, and in the neighbourhood of the hilus. This direction is dependent on the manner in which the spleen is suspended by its ligaments.

Ruptures of the kidney take rank as regards frequency in the fourth place; as isolated injuries they are rare, as the kidneys are well protected by muscles, connective tissue, and fat, and also by the vertebral column (Geill). They occur most frequently along with other injuries from being run over. Hofmann (1) mentions a case in which a medical man, going quickly, ran up against a wooden barrier, which caused fatal hæmorrhage from the kidney. Mittenzweig (Zeitsch. f. Med. Beamte, 1893, S. 616) reports a case of traumatic bleeding from the right suprarenal capsule, 24 hours after the patient had got caught between the buffers of railway wagons; the bleeding was internal, and was caused by rupture of the vessels of the right suprarenal capsule; there were also fractures of ribs, of a clavicle and thrombi of the middle intercostal arteries.

In injuries of the kidneys ending fatally, according to statistics collected by Kuster (Kuster, Die chirurgischen Krankheiten der Nieren, Deutsche Chirurgie, Liefg. 52b), death takes place from hæmorrhage in almost half the cases (in 30 out of 67 cases), and mostly from secondary hæmorrhage during the first four weeks, or from rupture of an aneurysm that has formed. From a medico-legal point of view it is important to know this.

Ruptures of the pancreas are less frequently traumatic than spontaneous from disease—mostly fatty degeneration—and may cause death from the bleeding that takes place (pancreatic apoplexy). Various views prevail as to the nature of pancreatic hæmorrhage. Zenker (11) looks on it as the cause of sudden death; Reubold (11) as a symptom of circulatory disturbances that have themselves caused death (Sachs). Kratter (45) investigated 33 cases, and came to the conclusion: "Pancreatic hæmorrhage is not the cause but the consequence of sudden death, and is not very rare when death is sudden. It has a diagnostic significance, inasmuch as it indicates a cause of death in which an agonal trauma occurs (spasm of the diaphragm), which affects the abdominal salivary glands." Further observations are necessary for the clearing-up of this question.

Injuries and ruptures of the hollow organs lying in the abdominal cavity, the stomach, intestines, the bladder, as well as all other organs carrying vessels—the mesentery and omentum—may all lead to death from hæmorrhage. Tuberculosis, ulcers of the mucous surfaces (round ulcer of the stomach, typhoid ulcer of the intestines, dysenteric ulcerations), all predispose to ruptures. For their occurrence it is necessary that a part of the gastro-intestinal canal shall be over-full of liquid, semi-liquid, or gaseous contents, and be forced against a solid body—the vertebral column—and kinked at the side so that the contents cannot escape. According to the laws of hydrostatics, rupture must then take place, and must always be at the weakest or diseased part. The following have been observed to cause fatal intestinal hæmorrhages: The lifting of a cask (Hankel) (48), a blow of the first against the abdomen (Bodgan) (49), manipulations during labour (Ciechanowsky) (50), and others. Friedberg (14) mentions a case of fatal hæmorrhage from the stomach from the improper use of an emetic. Dr. Graetz-Sobbowitz (52) (Aerztl. Sachverst.-Zeit., 1900, No. 5, S. 95) reports a case of fatal intestinal hæmorrhage from an accident in which a workman was engaged in lifting an iron rail with a lever, when the lever slipped, and he received a blow on the abdomen with it; he fell forwards, and by the evening was dead. At the autopsy a good deal of hæmorrhage was found between the layers of the mesentery, and the small intestines were also filled with partly fluid blood.

A GENERATION'S OBSERVATION OF DISEASE. (a)

By JAS. ORMISTON AFFLECK, M.D. Ed., F.R.C.P.,

Consulting Physician to the Edinburgh Royal Infirmary, etc.

Dr. Affleck remarked that since he first studied medicine great changes had occurred. The science of bacteriology had arisen, and had shown us the cause of many diseases, while in the more recent researches into immunity we were discovering the exact nature of many morbid processes. The chemistry of digestion had also thrown fresh light upon many of the most important diseases the physician encountered, while the introduction of

---

(a) Abstract of President's Valedictory Address, delivered before the Edinburgh Medico Chirurgical Society, November 6th, 1907.

Röntgen rays was an instance of the fruitful application of physics to medicine, and the same science had given us means of investigating the blood pressure, and the various methods of applying electricity in diagnosis and treatment. The study of the blood, too, had resulted in many valuable additions to our power of diagnosing morbid processes. He believed, however, that the older amongst his hearers, in particular, would bear him out as to the valuable information that could be derived by simple observation of patients. He did not mean only the facies of disease, but used the word physiognomy with a wider meaning, to include all the signs which were visible to the unaided senses

Take, for instance, cough. We could distinguish the short, suppressed cough of pneumonia, the dry, irritable cough of early phthisis, the hysterical cough, the barking cough of puberty, whooping cough, the clanging cough of ultra-thoracic pressure, the cough of chronic bronchitis, and he believed also that the cough of pyopneumothorax had a character of its own. Simple observation of the phenomena of disease, such as these, gave information of great value, and out of many instances which rose to his mind he might cite the case of a young clergyman who entered the consulting-room with the complaint of chronic indigestion, vomiting, lassitude and headache. Watching him as he spoke, the pearly glistening of the conjunctiva attracted attention, and led to an immediate examination of the urine, which showed that Bright's disease was the cause of his symptoms. Again, a business man who had always enjoyed the best of health presented himself for life assurance. It was noticed that his hair was rather dry and scanty, and there was a dull, pinkish, malar flush. These aroused the suspicion that he had diabetes, and this was found to be the case.

In typhoid fever, again, the patient's expression was often characteristic. In the Fever Hospital he noticed that the first note that his friend Dr. Ker made on the case of a newly-admitted patient was whether he "looked like" typhoid fever or not. As a result of experience, a physician gradually acquired what, for want of a better word, he would term "clinical impressions." Some possessed the faculty much more than others, and it was one of the most valuable assets it was possible to acquire. By clinical impressions he meant something which was quite uncommunicable to others; the physician himself could not tell why or how they came—they were the unconscious result of comparisons and recollections. Such impressions had often been of the greatest service to him both in suggesting to him fresh lines of treatment which had often proved successful, and sometimes in encouraging him to offer hope where the circumstances seemed desperate. Such impressions sometimes led one astray, but they were, nevertheless, of the greatest value, and the faculty of acquiring them ought to be developed as far as possible.

Next he wished to speak of the psychical aspect of disease, and of the importance of trying to discover what was in the patient's mind. It was hardly too much to say that there was no disease but had its effect on the patient's temperament. In some we found illness causing irritability and fretfulness, while in others the reverse change occurred, and the busy, restless, energetic man became an example of patient fortitude. Mental processes had a profound effect on the body; he instanced, as a case in point, a young girl in his ward whose constant high temperature aroused great anxiety until her appearance of well-being had suggested its hysterical origin. Subsequent events showed that it was one of those rare cases of hysterical hyperpyrexia.

The importance of mental effect in therapeutics was shown by the well-known story told of Sydenham. Having a patient whom no efforts of his could cure, he told him that there was only one physician who had made a study of his complaint, Dr. Robertson, of Inverness. The patient decided to seize this hope of cure, and posted the distance of six hundred miles, armed with a history of his symptoms, and an introduction to Dr. Robertson. When he arrived at Inverness he learned, with dismay, that not only did no Dr. Robertson live at Inverness, but that no practitioner of that name had existed there within the memory of the eldest inhabitant. As enraged at the deception which had been practised on him as he had been hasty in setting off on his journey, he hurried back to London and upbraided Sydenham. "But you appear better," said the doctor. "Yes, I'm better," replied he, "but no thanks to you for it, Dr. Sydenham." "You are better, thanks to Dr. Robertson, of Inverness," answered Sydenham; "I wished to make you travel with a definite interest, and I made you go to Inverness with the object of consulting Dr. Robertson, and travel back to London in order to abuse me." He could only see what was passing in a patient's mind by the exercise of the gift of sympathy, so that the cultivation of this should be one of our objects. If it were important to study the patient's thoughts, it should equally be remembered that the patient would study the doctor's face, and many were quick to perceive what was in his thoughts. It was only when he could detect sympathy and comprehension that he gave the physician his entire confidence, and without the patient's confidence it was difficult, or impossible, to do him good.

A PRELIMINARY NOTE ON A

SIMPLE OPERATION FOR UNCOMPLICATED OBLIQUE INGUINAL HERNIA IN YOUNG ADULTS (a).

By GEO. LYALL CHIENE, M.B., C.M., F.R.C.S. ED.,

Senior Demonstrator of Surgery, University of Edinburgh; Assistant Surgeon Edinburgh Royal Infirmary.

OBLIQUE inguinal hernias in children being admittedly of congenital origin, and due to the existence of a preformed sac, partial or complete, and ligation of the neck of the sac at the internal ring having been proved to be an efficient line of treatment, it is justifiable to suppose that if in young adults oblique inguinal hernia is also of congenital origin—*i.e.*, due to the existence of a preformed sac, a similar operation will prove satisfactory. The operation devised for the purpose consisted in an incision over the internal abdominal ring about half an inch above Poupart's ligament, with successive division of the muscular layers, exposing the neck of the sac, which was then divided and ligated. The second stage in the operation consisted in union of the wound, without an attempt to close the inguinal canal, or to remove the sac, and without interference with the integrity of the normal function of the internal oblique and transversalis muscles. Evidence from various sources was put forward to show that there was no essential difference as regards origin between so-called acquired oblique inguinal hernia which developes gradually, and the congenital form, which develops suddenly. In both classes of case it was argued that a preformed sac existed. Murray's observations on cadavers showed that in a considerable proportion of cases, where hernia had never occurred, there yet existed a passage large enough to admit a probe along the inguinal canal. The internal ring was normally closed by the valvular action of the internal oblique and transversalis muscles (as could readily be appreciated when, during the operation, the patient came out of the chloroform to some extent and began to strain), and it was held that, provided the sac was effectively dealt with, the natural function of these muscles would be regained and would be amply sufficient to maintain the closure of the internal ring. On the other hand, operations which involved suturing the internal oblique and transversalis with a view to producing closure in this way, interfered with the normal function of the muscles and the natural mechanism occluding the ring. The operation was devised for young adults, and the limit of age at which it could be performed with a good prospect of success depended on the tone of the muscles of the patient. The advantages of the operation were the absence of complications arising from manipulation of the sac and scrotum, and, owing to the position of the incision, the diminished risk of contamination. It was not necessary to keep patients in bed more than a fortnight or three weeks. As soon as the wound was firmly united it was better to allow them up so as to restore the function of the muscle closing the ring. The principle was insisted on that in oblique inguinal hernia a preformed sac was a necessity, and that unless this was present the internal ring would be kept closed by the valvular action of the muscles. From this it followed that the sac being closed, the normal muscular action would reassert itself. Operations which attempted to cure hernia by suturing the pillars of the ring, &c., deviated from this principle, and did not sufficiently take account of Nature's method of occluding the inguinal canal. Reference was made to a number of cases in which the operation had been followed by a satisfactory result.

THE LIMITATION OF MORTALITY FROM TUBERCULOSIS.

By W. R. MacDERMOTT, M.B.,

Medical Officer of Poyntz Pass.

An experience of forty years of tuberculous disease may justify me in expressing views of its nature, even though my knowledge of the literature bearing on it is extremely defective, in part from want of access to its vast and ever-increasing mass. Under the condition, there may be nothing new in what I have to say; it may be all a many-told tale, but, if so, it certainly is not adequately represented in the body of opinion which constitutes current formal doctrine, that which every medical man and every medical student is expected to know.

If that formal doctrine was simply speculative and academic, it might be allowed to pass; all our judgments are more or less of the nature, even where the necessity of action compels us to select one judgment, discarding or ignoring others. It is one thing, however, to do so consciously, another to do so at the expense of consciousness of what is ignored. The proposed, and far more than proposed, "war on the white scourge" is an instance of this; we form a judgment under some preconception, of the necessity for action against tuberculosis, but the merit and necessity of the action do not at all make the judgment a necessary one; it is in reality only one with many alternatives, which we have no right to discard or be ignorant of because they do not give us grounds for action, or grounds not at all sufficient to justify a vast expenditure of public money.

The position is not new; we have had experience of it in the past, and of the futility of a judgment based on imperfect knowledge. For long enough medical men stood helpless before small-pox. It might satisfy the anti-vaccinationists to say that the right thing was to have initiated a sanitary campaign against the scourge, isolation hospitals, sanatoriums, and so on; but that would have satisfied Sydenham as little as his successors nowadays. A sanitary campaign would have been all very right on general principles, but medical men would never have committed themselves to the opinion that it would have prevented or arrested epidemic small-pox. They would not commit themselves now to the opinion that, in the absence of vaccination, it would not occur, however perfect the conditions of sanitation might be. They would hold that isolation and isolation hospitals only met the case of the disease as it actually occurred, and had limited efficacy in preventing it spreading. What was early seen was, that it was limited by its own incidence, that experience of it was the most effective means of controlling the mortality from it. The adoption of inoculation rested on the observation that the disease was not a fatal one for the mass of persons under ordinary circumstances, that its fatality depended greatly on it selecting certain persons under certain circumstances. The general conclusion arrived at was that the fatality was a minimum in proportion as the experience of the disease was a maximum, and the conclusion was sound enough to base the practice of inoculation on. Looking on vaccinia as a modification of variola, the principle holds good for the artificial induction of the disease as the most effective means of controlling its mortality.

The received doctrine in respect of tuberculosis is that it is, unlike small-pox, a persistent morbid state, but I would suggest to the thinker on the subject to contradict tentatively every article of his faith; it is no sin to do so. We cannot say that small-pox is not a persistent state; it leaves behind a state of body which is certainly not the original one, as evidenced by loss of susceptibility to the disease. We do not call the new state morbid, although there may be no essential difference between it and the states we do apply the term to. Again, small-pox does persist as changed states of the skin and other organs in very gross form. That, of course, we put in a different way, but we cannot always draw a line between a disease as a primary affection and what it leaves behind—distinguish clearly between them. In the next place we may contradict the position that tuberculosis is a permanent morbid state in the sense small-pox is said not to be. Its typical form may be stated, in respect of invasion and course, as not in any essential respect different from typical small-pox. The form, fortunately comparatively rare in the human subject, is best seen when induced experimentally in susceptible animals. It is in both cases rapidly and more uniformly fatal than small-pox. How, then, does it come that a disease of such character is, relatively to its prevalence, under extreme limitation with respect to the mortality from it; in what direction are we to look for the restraints on its mortality?

In the present state of our knowledge of it, several answers may be given to the question which, though not very satisfactory, are taken together inconsistent with the doctrines at present in fashion. If we go back to the older writers we will find that they do not affirm, or deny, or were ignorant of, in a general sense, an initial cause for the disease, a contagious or infective agency which they were unable more precisely to define What, however, they had clearly in mind was, that certain morbid processes, once set up, were self-acting—had continuous operation independent of the exciting or contributory cause. What they said or supposed was, that a certain medium was the first and necessary condition of zymosis, and that the spoiling of the medium, say, the blood, or an element in it, under zymosis, led, in the case of tuberculosis, to a specific exudation from the blood. It was, however, only natural and logical, going back to what is now called the nutrient germ medium, to hold that it varied of itself independently of any extraneous agent exciting zymosis, and that diseased states, quite apart from zymosis, would arise from change in it. The case was not that of an organic fluid sealed up in a tube and found stable under the condition; the fluids in the actual case are undergoing metabolism from instant to instant in presence of a host of causes which might vary or derange the operation. Thus the old is a general position allowing the modern one of germ action as a particular case. The particular case meant that the medium was normal for the zymosis, but that did not mean that it was physiologically normal; the very state that favoured zymosis might be the true pathological antecedent and explain what is meant by predisposition. But the pathological antecedent is capable of morbid development *per se;* it is the essential factor, the zymotic operation, particular itself, only gives it some particular modification. On the other hand, while zymosis spoils the medium it operates on, the medium may be spoiled for the zymosis by the pathological development or by return to its normal physiological condition. Thus the old view that tuberculosis was due to a diseased state of the blood inducing a specific exudation, may be so far correct that unless some pathological change occurred in the nutrient media the tuberculous infection would not develop; it might be present indeed, or there might be exposure to it, but it would not act as a disease or cause of death unless as perpetuating and aggravating the prior condition itself, *per se* morbid, and, for all we know, capable of development on its own lines in the absence of the specific infection.

From the point of view, we may be justified in tentatively, at least, objecting to the position that the tuberculous infection is primarily itself a disease or cause of death, that it is so only as it interacts in a prior condition. We may conceive it as occurring in some animal system, including the human, as a normal event, not *per se* disturbing the normal state. This does not exclude the supposition that it may disturb certain organic systems on transmission from a system it does not disturb, since the nutrient media of the receptive system may be such as more easily gives the condition favouring development of the bacilli in number and virulence.

For the human system the question is whether the infection subsists, giving no pathological effects. We are so much in the habit of associating it with such effects that we never think of determining it as an initial occurrence not necessarily harmful in itself. If in any case it seems to be so, as, for instance, when transmitted from a healthy person, we pass the fact by. The logical conclusion would be for it, not as a rare exception, but as the general rule. If we proceed from this we will find that much of the obscurity enveloping the subject clears up. As our knowledge of the infection extends we get to see that our exposure to it is universal, and our experience of it almost equally so. Not only so, but the exposure is a common one for a large group of animals in contact with man, and the attempt to differentiate bacilli specific for each animal has utterly failed.

The response to the exposure, or the experience of the infection in man, is, of course, placed under limitation by the preconception that it is necessarily a disease; it is looked for only under the condition of some diseased manifestation or other. Even so, however, the manifestation, varying in degree from what is scarcely perceptible to rapid and fatal virulence, would justify the conclusion, or rather the judgment, conformable to our present knowledge, that the infection *per se* subsists essentially in a form consistent with normal organic integrity. It is of the utmost importance to take this view into consideration, since the presence of the infection in such form, while not disturbing normal integrity, may induce toleration of it, limiting thereby the mortality which, under some circumstances, it may cause. It is quite true that, in any case, the zymotic products of the tubercle bacillus affect the composition of the nutrient fluids, and thereby the life of the organic cell; but it is equally true that there is response or adjustment to the condition which, within certain limits, is only a case of the general physiological adjustment of the cell to the varying conditions to which it is normally subject. If for any reason the cell is unable to make the necessary adjustment, then the power for mischief of the tuberculous infection arises, but that adjustment can never be called into play in the absence of the occasion for it. The cell has normally the power of reacting to a host of circumstances, but the power, even though connate, in practice depends on experience of the circumstances. If the cell thus happens to have no experience of variation of temperature, its potential capacity of accommodating to the variation in the absence of experience of it does not save it when suddenly exposed to change of temperature.

As a potential cause of death, tuberculosis is to be judged by its typical form. Taking the form as invariably fatal, the restraint on the fatality is to be judged from the fact that infection invades the infant system in the first few months of life without causing any significant fatality. It does not in the least matter whether the proportion of infected infants is taken as 30, 50, or 100 per cent.; the evidence is wanting in any case of a fatality corresponding to the potential form. The extent of incidence of the infection is taken under the preconception of some morbid sign, or of the presence of the bacilli being necessary to determine it. The reaction to tuberculin is a more certain test, but, as far as I know, has not been sufficiently extensively applied to give experience of infection in infants in adequate numerical terms. That, however, does not matter so long as it is left undetermined whether the infection is permanent or not, whether, as occurring in a transient, imperfectly developed or speedily suppressed form, it does not prevent recurrence, or induce toleration or modification of itself in varying degree under recurrence. From personal observation of many hundred cases under the condition of non-discrimination between slight and severe, I venture to say that far and away the most prevalent form is recurrent, the recurrences being independent or distinct in the pure pathological sense. But, as I conceive, they are not independent in another sense; the experience under recurrence engenders as a sum effect and *cæteris paribus* toleration of the infection. The difficulty in the way of understanding this seems to me to arise from attention being concentrated on the severe permanent and progressive cases. It must, however, be allowed that these cases constitute in reality only a fractional part of the experience of the infection; they do not at all give us a general view of the experience. I am venturing again on expression of personal observation in saying that in a large proportion of the severe and fatal pulmonary cases factors apart from the mere tuberculous infection are more or less clearly in evidence. A statement which will receive so much corroboration from others hardly needs excuse. Another point will receive like corroboration. I have come across cases in which life was prolonged amazingly, although both lungs were riddled through and through with disease; not a square inch sound, and other cases rapidly succumbing although the greater part of both lungs were, apparently, at least, quite sound. The opinion that the difference was in proportion to induced tolerance may stand until we can form a better one.

A great many of our cases contradict the supposition that the system is poisoned by the infection or by the products of the bacilli and as many that death is caused by destruction or alteration of tissue. So far, however, as both causes exist and co-exist in some complex relation, it seems clear enough that the induction of toleration applies to govern the course of even the most severe cases. It would indeed be unnecessary to reason that experience of the infection induced tolerance of it, and that the induced tolerance was the chief restraint on an otherwise extremely fatal disease, if our formal doctrine and public opinion as based on it did not propose action directed to "stamp out" infection. The infection of small-pox was not stamped out; it, or a modification of it, was used to control itself in the light of the fact that it was so controlled.

My main position here is an expression for the infection at limit, to use a mathematical term. At an inferior limit the infection occurs in a transient and quickly-suppressed form, and that is only to give the series under which it occurs legitimate extension.

"Two calves "(" Second Interim Report of the Royal Commission on Human and Animal Tuberculosis," p. 9) "each received in the form of an emulsion the same estimated dose (9,000 bacilli) of the same emulsion of virus I. One calf died of general progressive tuberculosis, while the other, killed in apparent health, showed only a very limited retrogressive tuberculosis." The report goes on to make a more general statement to the same effect. Now, the latter calf would have reacted to tuberculin, but would it if the experience had been a transient one, leaving no effects, or effects completely recovered from? Or, taking the case of insusceptibility, the dose being supposed to be that ingested under ordinary exposure, are we to attribute it to something we do not know or something we do know—induced tolerance? The Commissioners say that they excluded prior spontaneous tuberculosis in the animals they experimented on as far as possible, but how could they exclude passing intestinal infection having no effect other than that of inducing tolerance? Or how could we in the case of children who, for all we know, are swallowing thousands of the bacilli and becoming accustomed to the thing as they would to mercury or opium, if constantly administered in harmless doses? The Commissioners speak of a "combat between the pathogenic energies of the bacilli and what has been called the resistance of the tissues." But the reaction we call resistance needs experience of the action resisted, and we are cognisant enough of the experience in general to know that, whatever other factors may enter its operation, it is not necessarily constant, but efficient through repetition.

Our line of inquiry, I conceive, should be directed to ascertain the extent of the tuberculous infection in the human subject as a normal and unavoidable occurrence. That it develops a formidable disease is quite compatible with the position that it is the most efficient agency in limiting the disease and the mortality from it. I have long ago come to the conclusion that tuberculosis in a transient form is almost universal among infants, often as an intestinal infection. But for some reason there is either connate or rapidly-induced tolerance of the infection in infancy; the mortality from it is out of all proportion less than it is in infected adults or adolescents. Nevertheless, as is stated in the report cited, "the same dose of the bacilli produces less effect on an adult animal than on a young calf. This result we may explain as due to the powers of resistance of the tissues increasing with age." The result, however, may be more easily explained by saying that tolerance acquired in infancy persists to enable the adult to resist the effects of the larger dose. But the tolerance is no doubt to be taken in relation to the "virulence" of the bacilli, a term expressing a variable distinct from dose. Induced tolerance, so far as it goes, protects the adult, but other factors arise both in the bacillus as an operating agent and in the individual it operates on. These factors, as prominent, obscure tolerance; we cannot, or do not, use that in treatment of the disease, and so incline to ignore it when it appears as a failure to us. Nevertheless, it may be, in reference to the potentiality of the disease and the mortality from it, the main agency averting a vast destruction of human life. What tuberculosis now does is as nothing as compared to what it would be capable of doing if under no restraint arising in itself.

While, of course, admitting that everything should be done for the individual patient, I have no faith in a "campaign" against tuberculosis resting on the notion of abolishing or diminishing the specific infection and exposure to it. Much, indeed, of what I see in print seems utterly absurd to me—fit to figure in mediæval medical lore. Treating the individual or protecting him against infection by any of the methods proposed is not a campaign against tuberculosis. We must learn, as in the case of small-pox, to use the infection itself before we can make any impression of a permanent nature on the mass incidence of the disease.

OPERATING THEATRES.

NORTH WEST LONDON HOSPITAL.

Two Cases of Chronic Abscess of Maxillary Antrum.—Mr. Mayo Collier operated with the most satisfactory results on two cases of abscess of the maxillary antrum of long standing. Now some six months have elapsed, and the two cases are entirely free from antral discharge, pain, or discomfort of any sort. The first case was one of a woman, æt. 48, who had had a discharge from the right antrum for the last eight years. She had to wash the cavity out daily with lysol lotion to prevent the discharge becoming offensive. An opening had been made in the site of the first molar tooth, and a drain was established here by a plug fitted to the false teeth. The case was apparently one due to an abscess at the root of one of the molar teeth bursting into the antrum and so infecting it. The tooth had been removed and the antrum washed out and drained by establishing an opening near the site of the first molar tooth. The patient now complained of the constant annoyance of having to wash out the cavity daily, and the offensive condition of its contents unless the cleansing was regularly performed. On the date of the first visit Mr. Collier washed out the cavity himself through the opening in the alveolus, and noted that the result showed flakes of green offensive pus and *débris*. He advised an immediate radical operation, and stated that no hope could be entertained of a cure or a restoration to the normal of the lining membrane by any further washing and disinfectants. The case was accordingly admitted, and Mr. Collier proceeded to operate by the following method. A long strip of flat sponge was packed in the inferior meatus of the nose from front to back with the double object of preventing blood passing into the pharynx, and also of preventing any damage to the septum when breaking through the inner wall of the antrum into the lower meatus. Mr. Collier pointed out that this was one of the most important steps of the whole operation, because it afforded not only a guide to the lower meatus but also a buffer to the impact of the chisel or drill that it was necessary to use in breaking through the inner wall of the antrum. A sponge was next packed in the buccal cavity so as to prevent any blood entering the pharynx. This was followed by a transverse incision at the junction of the lips and gum in the site of the canine fossa; the tissues down to the bone having being separated with an elevator and retracted up and down, the cavity was first found by introducing a protected gimlet. As soon as the cavity was made sure of, a cone-shaped burr was introduced in the site of the puncture, and the opening gradually enlarged until it was of sufficient size to admit the little finger of the left hand. By this means every nook and corner of the cavity could be carefully explored and the diseased tissue or polypoid granulations removed with a curette. Mr. Collier pointed out that it was not necessary to denude the interior of its periosteal covering; all that was necessary was to curette softly the whole lining membrane of its thickened and diseased covering. This being done the most important part of the whole procedure was undertaken, namely, that of making a large communication between the cavity of the antrum and the floor of the nose in the site of the lower meatus. If the outer wall of the nose, as it frequently is, he said, is thin, an elevator or chisel will pass easily through it from the floor of the antrum, but often the bone is of considerable thickness, and the gimlet has to be used at several spots before the elevator or forceps can pass easily. When a large opening had been established the sponge was withdrawn and the *débris* of bone and mucous membrane curetted and removed so as to establish perfect freedom from the nose to the antrum. The bleeding from the antrum and nose having been arrested by packing for a short time, the opening in the canine fossa was closed by stitching the periosteum and mucous membrane separately, and a pad was placed on the cheek so as to prevent displacement of the parts. The patient was removed to bed, and instructions were given that no washing or interference of any sort be adopted. Mr. Collier said this was a common-sense procedure suggested by the ordinary principles of surgery, and that no lesser operation could be expected to bring about resolution of the lining membrane of a cavity so peculiarly situated as that of the antrum.

The second case was that of a man, æt. 50, who had suffered from stinking discharge from the nose for several years before being treated. The fact of an abscess existing in the antrum was discovered by his local medical attendant, and a tooth having been removed the cavity was washed out in the usual way. This was not followed by resolution, and ordinary daily procedure had to be adopted to prevent the patient being offensive to himself and to others. Mr. Collier having ascertained by washing that the discharge was still persistent and offensive performed an almost identical operation as in the previous case with a similar most satisfactory result.

THERE are no fewer than 555 scarlet fever patients in the Birmingham city isolation hospitals. This is an increase of nineteen in the total recorded a week ago, when the aggregate was 536. Last week there were 71 fresh cases of the malady reported, as compared with 74 for the previous seven days. The type of the disease is not virulent, and consequently the case mortality is low, only two deaths attributable to the disease having been registered during the past fortnight. The general health of Birmingham is not bad, judged from the death rate, which last week was 15.5 per 1,000 of the population, the zymotic death rate being 1.2.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, NOVEMBER 8TH, 1907.

Sir THOMAS BARLOW, Bart., in the Chair.

Mr. J. HUTCHINSON, jun., showed a case of

TRIGEMINAL NEURALGIA.

in which the Gasserian ganglion had been excised for recurrence of the pain after intra-cranial neurotomy of the second and third divisions of the fifth nerve. The patient had had characteristic trigeminal neuralgia for seven years. Three years ago the inferior dental nerve had been resected through the ramus of the mandible. The pain had been relieved for a time, but 18 months later, on account of recurrence of pain, the second and third divisions had been cut within the skull. When the patient came under Mr. Hutchinson's care about a year later the pain had come back, and there was some return of sensation in the area of distribution of the second division. The Gasserian ganglion with the exception of the ophthalmic part was therefore removed. Mr. Hutchinson showed the case to demonstrate the comparative valuelessness of mere division of the nerves, whether within or without the skull. He referred to Abbey's operation of intra-cranial neurectomy with occlusion of the foramina with indiarubber.

Mr. CHARLES BALLANCE had several times done the operation of removal of the Gasserian ganglion with preservation of the ophthalmic part, and had found it satisfactory. He had recently had an opportunity of seeing Abbey's operation carried out by its originator. In some cases there had been a return of pain in five years, and at a second operation it had been found that a few filaments of the nerves had penetrated the foramina and restored the continuity of the trunks in spite of the rubber plugging. The great advantage of the operation was that it was extradural. Mr. Ballance had lately had to operate again upon a case in which four and a half years earlier he had done intra-cranial neurectomy and plugged the foramina with gold leaf. At the second operation it appeared that union of the nerves had occurred. In spite of such liability to recurrence he considered the operation compared favourably in many ways with the intra-dural methods.

Mr. HUTCHINSON replied.

Dr. BERTRAM ABRAHAMS showed a case of

MYOPATHY.

The patient was a man of 43; he gave no family history bearing on the case. There had been increasing weakness of the legs for 17 years and latterly of the arms also. There was wasting of the biceps, pectoralis major, quadriceps, gluteus maximus, and supraspinatus on both sides, and to a less extent of the pronators flexors of the left forearm, right hypothenar muscles and latissimus dorsi, together with the adductor and abductor muscles of the thighs. There was hypertrophy of the deltoids and serrati, and to a less extent of the triceps, infraspinatus and rectus abdominis. The deltoids did not respond to electric stimuli, but the reaction of all other muscles was normal. The erect posture was only maintained with much lordosis; the gait was markedly straddling. Dr. Abrahams said that the case seemed to be most nearly allied to Erb's juvenile form of muscular atrophy.

Dr. A. M. H. GRAY showed a woman of 41 with

TYPICAL SIGNS OF MYXŒDEMA.

who 16 years earlier had had exophthalmic goitre. When seen three years ago the patient had ascites which cleared up under treatment with thyroid extract. It occurred slightly when the treatment was temporarily discontinued. The thyroid gland could not be felt; a small papillary growth the size of a pea was present on the dorsum of the tongue just in front of the foramen cæcum. It was not thought to be of thyroidal nature.

Drs. Parkes Weber, Herringham, and Garrod discussed the case. Dr. Gray replied.

Mr. T. H. Openshaw showed a case of

RECURRENT DISLOCATION OF BOTH SHOULDERS CURED BY OPERATION.

The patient was a man of 27, an epileptic, and had had numerous dislocations of the shoulders during the fits. Many methods of treatment were tried without success. Finally the subscapularis was detached from its insertion into the humerus and united to a part of the deltoid. Mr. Openshaw had done this operation three times, in all cases with permanent success.

Mr. J. Hutchinson, jun., discussed the case.

Dr. Herringham showed a case of

NEURITIS OF THE BRACHIAL PLEXUS,

probably resulting from arthritis of the shoulder. Evidence of involvement of the whole plexus had followed within a few weeks upon an apparently rheumatic affection of the joint Dr. Herringham regarded the lesion as a perineuritis spreading to the nerve sheaths from the capsule of the joint.

Dr. Sidney Phillips referred to the frequency with which signs of joint affection are found in cases of neuritis.

Dr. Herringham also showed a case of "splenic anæmia," in which there was widespread pigmentation of the whole body.

Dr. Murray Leslie showed two cases of "congenital heart disease" in adults.

Dr. J. Fawcett read a short paper on the

TREATMENT OF PNEUMOTHORAX BY ASPIRATION UNDER THE X-RAYS.

He gave the history of a case in which the operation was done under the X-rays so that the necessary amount of suction could be exactly adjusted and no undue negative pressure be produced. The lung could be watched expanding as the air was withdrawn. He considered such treatment would in selected cases effect a considerable shortening in the course of the condition, and that it was therefore justifiable to incur the slight risk entailed.

Dr. Parkes Weber and Dr. Sutherland discussed the paper, and Dr. Fawcett replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held November 6th, 1907.

The President, Dr. Affleck, in the Chair.

Mr. Cotterill showed:—(1) Specimens from a case of panhysterectomy for fibroids and ovarian dermoids; (2) Pyosalpinx complicating appendicitis; (3) Spindle-celled sarcoma of foot; (4) Hydatids of liver; (5) Cerebellar tumour, successfully removed.

Mr. Cotterill also showed:—(1) A patient who, after being thrown from a gig, developed an orbital angioma, with marked proptosis of the right eye, and a pulsatory swelling giving rise to a bruit which could be heard both by the stethoscope of an observer and by the patient himself. In such cases ligature of the carotid had not always proved satisfactory on account of the very free anastomosis which took place. In the patient in question there was very considerable evidence of anastomosis, particularly with the nasal branches of the facial artery. He had, however, been encouraged by the fact that pressure on the common carotid checked the pulsation and bruit, and therefore the common carotid had been ligatured. The result was entirely satisfactory, the proptosis having disappeared, and the movements and aspect of the eye having become quite normal, except from some weakness of the sixth nerve. (2) A case of sarcoma of the chest wall. As in most cases of this kind, the growth of the tumour had been very irregular as regards its rapidity. It had begun in the posterior triangle of the neck, and was probably a lympho-sarcoma. The tumour was now very exclusive, and involved a large area of the chest wall. It was proposed to treat the case by Röntgen rays. In a previous case of similar nature very great improvement—indeed, almost complete disappearance of the sarcoma—had resulted from X-rays. On the interruption of the treatment, however, recurrence took place.

Mr. Alexis Thomson showed:—(1) A child with spontaneous fracture of the lower end of the femur, probably the result of osteomyelitis fibrosa. The fracture took place as the boy was standing in the street, without any violence having been employed. In spontaneous fractures of this kind union took place readily, but there was no means yet known of preventing recurrence. (2) A child with an unusual form of greenstick fracture of the forearm. The fracture was not, strictly speaking, greenstick at all, but a complete break of both bones. Union had not taken place, and there was extreme angular deformity. In fractures of both bones of the leg in children, it was sometimes extremely difficult to obtain union, and metal supports had to be used to prevent riding. He proposed to operate in this case, and unite ends of the broken bones. In the arm shortening was of little consequence; hence he would be able to remove the bone pretty freely, so as to get good union.

Dr. Robertson showed (for Mr. Stiles):—(1) A patient after extensive operation for epithelioma of the floor of the mouth. The tongue and the glands had been removed previously. (2) A patient, æt. 80, after operation for malignant disease of the upper jaw. In this case a preliminary laryngotomy had been performed. (3) A case of renal calculus in a patient who had suffered from Potts' disease of the spine.

The President delivered his valedictory address. After thanking the Society for the honour they did him in electing him to fill the presidential chair, he referred with gratification to the fact that during his term of office a large number of communications had been made by the younger members of the Society. This was as it should be, for the future of the Society depended on its younger members. In taking leave of the Society as its President, he wished to speak, however, not of the past, or of the future, but of the present, and to lay before them some results of the experience of more than

A GENERATION'S OBSERVATION OF DISEASE.

Dr. Affleck concluded his address, which was listened to with much appreciation, by expressing his wishes for the continued prosperity of the Society, and the security he felt that it would be in good hands, as he vacated the chair to allow Dr. Ritchie to ascend it.

(A full abstract of the President's address will be found on page 521.)

Dr. Allan Jamieson, in moving a hearty vote of thanks to Dr. Affleck for his conduct in the chair during the past two years, spoke in appropriate terms of the courtesy and tact with which he had guided the affairs of the Society, and the charming valedictory address he had delivered. Mr. Cotterill seconded the motion, which was carried by acclamation.

Mr. George Chiene then read a preliminary note on a

SIMPLE OPERATION FOR UNCOMPLICATED OBLIQUE INGUINAL HERNIA IN YOUNG ADULTS,

which will be found in another column, page 522.

The paper was discussed by Messrs. MacGillivray, Scott Carmichael, Dowden, Struthers, and Cotterill, and Mr. Chiene replied.

The following were elected office-bearers for the ensuing season:—President, Dr. James Ritchie; Vice-Presidents: Mr. C. W. MacGillivray, Dr. Byrom Bramwell, and Dr. Geo. Hunter; Council: Prof. Harvey Littlejohn, Dr. Aitchison Robertson, Dr. Keppie Paterson, Mr. W. Guy, Dr. Affleck, Mr. Berry, Dr. Gulland, Dr. Ker; Treasurer: Mr. J. W. Dowden; Secretaries: Mr. David Wallace, C.M.G., and Dr. F. D. Boyd, C.M.G. (editor of "Transactions"), and Dr. Wm. Craig.

Royal College of Surgeons, Ireland.

We are asked to announce that, on and after January 1st, 1910, all examinations for the Fellowship will be conducted under the scheme now known as Grade I. No candidate after the above date will, under any circumstance, be admitted to examination for the Fellowship of this College under the scheme now known as Grade II., which will then cease to be used.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, OCTOBER 25TH, 1907.

The President, A. R. PARSONS, M.D., in the Chair.

THE NITROGENOUS METABOLISM IN A CASE OF MYELOGENOUS LEUKÆMIA.

THE PRESIDENT read a paper on the above subject.

Dr. WALTER SMITH said it was not usual to discuss the Presidential Address, but he thought it would be unbecoming to pass over without remark a paper which marked a departure in the transactions of the section. It was a courageous attempt to investigate one of the darkest corners of pathology, the full investigation of which would tax the resources of the most skilled chemist. It was no disparagement of the paper to say that it did not lead to any definite conclusion. The same might be said of the general literature of the subject; and it might be safely asserted that up to the present chemical investigation failed to throw any light on the cause of leukæmia. The subject, moreover, was only part of the much larger subject of the general effect of diseases of the blood on metabolism, the metabolism generally taking the direction of catabolic destruction. Before they could get any general light on the subject, they must take into consideration other affections, such as gout with its uncertain relations to uric acid. More important than even the serious loss of proteins which had been observed in very acute cases of leukæmia, but not definitely in the chronic cases, was the question whether there was any distinction to be drawn, chemically or otherwise, between lymphatic and myelogenous leukæmia. There was, at any rate, one curious difference in regard to the nature of the cells that were found predominating in the two forms. Generally speaking, comparing the leucocytes with the large neutrophile cells, they were distinguished by a lesser chemical activity, and it would almost seem as if the chemical activity of the leucocytes in the normal body was held in check by anti-enzymes in the blood. They had become familiar with the doctrine that probably every cell in the body was, as it were, capable of eating itself. The chemical changes in the blood were so diverse that it was almost impossible to throw any light on the subject. All sorts of extraordinary things had been reported as existing in the blood. The xanthin bodies were well represented in the blood of leukæmia, but there were other bodies which might be *post-mortem* products. The solid exudate in acute pneumonia underwent resolution with puzzling rapidity; that was probably due to autolytic action, and we might probably look in that direction for the explanation of unresolved pneumonia. Dr. Parsons had been unable to trace any connection between uric acid and the leucocytes in leukæmia, and the fact that nitrogenous bodies in contact with the blood might furnish non-nitrogenous products showed how cautious they should be in interpreting the results of nitrogenous metabolism.

Dr. MAGEE FINNY said the subject opened up a great range for discussion. The practical point as to the X-rays being one of the great causes of improvement, if not the sole cause, was very important. It was not so long since the rays were only applied for diagnosis; cases in which they had been used as a means of therapeusis were not very numerous, and it seemed very remarkable that such results had been obtained in the case. A relationship between the elimination of uric acid and the white cells had been found; that, however, was valuable negative information for future observations.

Dr. PARSONS replied.

DR. TEED, the City of London analyst, in his recent quarterly report, mentions that the highest percentage of adulterated samples was in drugs bought with prescriptions. Out of seven prescriptions purchased, six were not made up in accordance with the demand of the purchaser, showing 85 per cent. of the prescriptions to be wrongfully compounded.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 10th, 1907.

PHLEGMASIA ALBA DOLENS.

IN spite of the progress of antisepsy and of obstetrical asepsy, which have diminished and almost removed puerperal complications, there is one exception, however, and that is phlegmasia. According to Boissard this affection is more common to-day than ten years ago, and is observed more frequently in private practice than in hospitals, where the women generally return to their homes before phlegmasia sets in.

Facts, parodoxical in appearance, would seem to prove, says Dr. Keim, that phlegmasia is not always due to puerperal infection. If on the one hand, it is observed in the course of convalescence of normal confinements, it is rare in certain cases of grave genital infection.

In the production of thrombosis, says Charrin, the presence of a germ is by no means indispensable. The blood can coagulate under the influence of the fibrin-ferment of the leucocytes in contact with the fibrinoplastic of the product. This coagulation, under the influence of chemical elements, can take place in two periods of puerperality; after delivery, under the influence of the chemical elements contained in the uterus itself; during the last weeks of pregnancy, under the influence of chemical elements of the neighbourhood and notably the intestine.

The increase of the coagulation of the blood during pregnancy, is due, outside the transformation of the liver, to the composition of the blood itself, which is rich in fibrin. This excess of fibrin persists a certain time after delivery; a favourable adjuvant in hæmorrhage, it can become an element of intravascular coagulation in retention of clots, exudation of serum and above all, after intra-uterine injection of salt water or corrosive sublimate. The blood of the uterine vessels is frequently put in contact, through the placental wound, with the products contained in the uterus; albuminoids, fibrinous clots, and for this reason phlegmation has been frequently observed following placenta prævia. Various are the conditions, consequently, outside infection, that would explain the frequency of abdominal venous coagulations and phlegmasia following delivery affecting either the uterus, the liver, or the blood, which do not exist after miscarriage.

The chemical causes have also their importance. They act by exaggerating the physiological thrombosis after delivery, and produce phlebitis of the uterus with subsequent extension to the lower limbs.

THYROID INSUFFICIENCY.

The slight symptomatic manifestations of thyroid insufficiency should be known to the medical practitioner in order for him to be able to apply the treatment of opotherapy. Dr. Henri de Rothschild has just published an interesting review on the stigmata of insufficiency of the thyroid gland.

Transitory Œdema.—Without any trace of albumin the affection is manifested by white, painless and elastic œdema, localised chiefly on the eyelids, the forehead, the malar region, and sometimes on the feet. This œdema returns more or less frequently, and is observed in the morning, after some annoyance, fatigue, migraine, or the menses. The repetition of these little signs have a certain diagnostic value.

Caloric Troubles.—These depend on the decrease of the thermogenic function of the thyroid body; but before assigning to them a symptomatic value the urine should be examined, for in cases of albuminuria they are also observed.

In any case they consist in a sensation of cold, particularly in the feet, but also over the whole body or in the back, the thighs, or in one or other of the extremities. The patient complains constantly of cold, and covers himself up in mantles or shawls and requires several bed coverings at night with the hot water bottle.

In these patients, the extremities are pale, the hands are cyanosed, and chilblains are frequent.

Other patients complain of shivers running through their whole body, especially the back, at certain moments in the day, generally towards four or five o'clock in the evening. They feel a sensation of iced water running down their back and limbs.

In a certain number of patients, the central temperature falls somewhat below the normal, particularly at night, and the slightest draught produces rheumatic or neuralgic pains, which we call lumbago, wryneck, migraine.

All these patients complain of fatigue in the morning; it is with reluctance they leave their bed and only recover their normal condition about half an hour after rising. They are also easily fatigued after walking some distance. This symptom is also found in neurasthenia.

Headache.—This symptom assumes two forms; frontal or occipital. Frontal headache resembles that of acute coryza, while in the occipital form the pain is over the seat of the occipital nerve, and resembles neuralgia. Generally more intense in the morning, it disappears in the evening or after a copious repast. In these patients are also observed muscular pains occupying different points of the body; the thighs, the intercostal muscles, those of the back of the neck, the lumbar region, etc.

Physical and Mental Insufficiency are frequently met with in these cases. A small number of internal secreting glands regulate the physical and intellectual development of a child, and in this the thyroid gland plays a capital rôle. Consequently a default in the function of the thyroid retards the growth and frequently the intelligence of the child. According to M. Hertoghe such children have difficulty in learning arithmetic and orthography, while stammering, incontinence of urine and cryptorchidia are freqeunt.

All of the above permanent signs of thyroid insufficiency are not necessarily to be found in the same individual, and one of them alone should not be considered as a basis for diagnosis, but where two or three are observed together they should attract attention.

GERMANY.

Berlin, Nov. 10th, 1907.

At the Society for Innere Medizin, Hr. E. Barth read an interesting paper on

The Physiology of the Tonsils and the Indications for their Removal.

He said that at present ideas as to the functions of the tonsils were not at all clear. Whilst one looked on them as indifferent structures, another considered them to be a protective apparatus against infection. From this want of clearness arose uncertainty as to the surgical treatment of the organs—for example, as to their removal in affections of the ear. As recent investigations had shown, the tonsils were composed of the same tissues histologically as the lymph glands, that they had therefore the same office in the organism; besides this, they had some macroscopical peculiarities that would be spoken of later. As regarded the function of lymph glands, the lymph was freed from foreign bodies such as micro-organisms, etc., in passing through them; they served, therefore, as a protective apparatus. Whether they possessed an internal secretion was still uncertain. The lymph glands further served for the production of lymphocytes. The tonsils would probably fulfil similar functions, the filtration of the lymph that poured through, and the production of lymphocytes. They had also the peculiarity of superficial position, and the formation of cells on their free surface. A stream of lymphocytes flowed through their epithelium, which formed a protection against the entrance of infectious germs into the interior of the tonsils. As it was assumed that the lymphocytes had no independent movement, it was believed that they were carried outwards by a stream of fluid. More recent researches, however, had shown that lymphocytes had an active independent movement; whether, however, any discharge of fluid took place was questionable. No epithelial openings through which the lymphocytes could pass were present on the surface of the tonsils. As pointed out above, the macroscopical structure was peculiar—an enlargement of the superficies by numerous lacunæ. Altogether, therefore, the tonsils, along with their character of lymph glands and the stream of lymphocytes, possessed a large surface and a strong secretion. The action of this structure and of these physiological properties of the tonsils was that of a mechanical protection against infection, and, moreover, chemical, fermentative, and antiseptic properties have been ascribed to them; but these had not been proved with certainty. The tonsils did not act phagocytarily. There was no evidence that the tonsils were the sites of blood formation.

Now as regarded the clinical properties of the blood in hypertrophy of the tonsils, we found an increase of the eosinophiles, a diminution of the neutrophile-polynucleated cells; but no specific influence on the formation of blood could be assumed at present. The tonsils were, however, by no means indifferent structures, as was assumed by many. They passed through a development dependent on age. In the youth of the individual they were in active function; in old age they underwent involution, as the protection they afforded was not so necessary as in early life. But the most dangerous general infections affected the tonsils. How was this to be brought into unison with the above views? The lymph glands were certainly protective organs, and yet they became flooded with infective material. It was further to be noted that the affections of the tonsils were often secondary. It had also been shown by experiment that foreign material escaped outwardly through the lymph glands. When micro-organisms were found in the tonsils, therefore, it must not be said they were the ports of entry for them, as they might have been carried there from the interior. Pathological changes in the tonsils did away with the protective function, and even caused them to act in a contrary manner.

Our therapeutic measures must be based on our knowledge of the functions of the tonsils. Healthy tonsils must, of course, be retained; those loaded with foreign detritus must be cleansed. In case of relapsing inflammations of the organs we must ascertain whether the inflammation was secondary; hypertrophy, even in itself, was no ground for removal of the tonsils, as, so long as they were composed of normal adenoid tissue, their protective power was increased. Tonsils should only be removed when the enlargement was accompanied by marked local disturbance, as upon the hearing. Children with enlarged tonsils were in greater danger in acute infective diseases, especially in scarlatina. Here the tonsils should be removed, and the removal should be done thoroughly. It was frequently done imperfectly, and a re-growth took place.

In removal it sometimes happened that the tonsils were so thoroughly taken away that firm cicatricial tissue formed to the detriment of the adjacent parts. The proper way to do this was to remove all above the level of the mucous membrane, so that that was retained intact.

AUSTRIA.

Vienna, Nov. 10th, 1907.

Glaucoma.

Chalupecky in his lectures maintains that traumatic glaucoma is a rare occurrence. The internal pressure of the bulb resulting from cicatrices of the cornea, occlusion of the pupil, luxation of lens, etc., are temporary conditions following an accident that frequently occur and can immediately be relieved. Glaucoma is a more serious affair, and might arise as a secondary disease.

We cannot refuse to accept that some cases of traumatic glaucoma sometimes appear, and among these the older authors supply us with a few published cases. Graefe expresses himself in similar terms, and closes by saying that you will hardly ever meet with traumatic glaucoma in a healthy eye, but as a secondary result you may.

Landesberg records one case of considerable interest in this respect. A young officer, æt. 46, was engaged in the war of 1866 when suddenly a bullet whizzed past his left eye without actually wounding it, but he became instantly blind with it while he continued to shoot with his right till he got his left leg smashed and had to be taken to hospital, where Graefe confirmed the glaucoma. This is a case that must be received with caution. It is possible that this eye was glaucomatous before he entered the battlefield, and as he shot with the right eye it is very probable that no notice was taken of the glaucoma till the accident.

At a later date, 1881, Ferber relates how a boiler-maker had his left eye injured with a splinter of iron and was blinded. In 1887 a similar accident happened to his right eye, which hitherto had been considered sound. On examination four weeks after the accident vision of left eye = able to count fingers at a metre distant; right eye, able to count at 1½ metre distance; tension, one degree harder, iris striated, opacity, retina covered with a white exudation in which was extravasated blood, and excavation of the papilla. Iridectomy was performed with resulting bleeding from the yellow patches. After nine weeks residence he was dismissed with vision = $^{3}/_{6}$ The glaucoma in this case is attributed to a traumatic irritation of the secreting ocular nerve producing a neuropathic hypersecretion with final intra-ocular pressure.

More recently Praun recorded one from Fuch's clinic of a boy who got the eye injured with a piece of iron, producing ciliary injection, opacity of the vitreous humours, hyperæmia of papilla, and veins, while the arteries were observed to pulsate; the outer half of the retina became detached and the tension was increased. Pilocarpin was administered and the retina subsided, but rose again after a short cessation worse than ever. The glaucomatous process increased, iridectomy simply relieving tension. This may be considered a veritable case of traumatic glaucoma complicated with separation of the retina, probably due to the irritation of the tensor and intra ocular pressure.

Garnier relates the case of another boy, æt. 11, who got a stroke on the eye followed by intra-ocular tension, and within ten days the eye became so staphylomatous that it had to be enucleated. The vessels were found in a hydræmic and swollen, or dilated, condition. The cause in this case seemed to be a blocking of the lymphatic vessels.

Sala endeavours to explain the cause of glaucoma by telling how he commenced to operate on an eight year child for a soft cataract, and when he had pierced the cornea no fluid came out, but the tension was instantly relieved. His inference is that the lens swelled and the corneal-iris angle became mechanically closed. The thick colloid mass that forms in the anterior chamber of the eye is an important factor in the production of glaucoma. Sometimes, however, the serous iris is the cause of the tension, although it is attributed to an increased secretion of fluid, but the real cause is more probably the albuminous colloid substance. In slight cases of glaucoma warm compresses, massage, and puncturing the anterior chamber will increase the circulation and relieve the stoppage in the corneo-iris angle, and thus avert a calamity. Intra-ocular tension after contusion is relieved in a similar manner. Experiments with eyes prove that albuminous fluids do not pass easily along the Schlemm canal; thus a quantity of albuminous fluid in the anterior chamber produces first a congested state of the fluids of the eye, compressing the vessels and producing hæmatic stasis, followed by closure of the corneo-iris angle and increased tensor that results in glaucoma.

Tuberculosis.

At the conference Panwitz discussed the cost of public sanatoria in the struggle with tubercle. A good sanatoria should be erected for £200 per bed.

Rumpf thought sanatoria were like "Kirks" or schools, and should be built substantially without consideration of cost.

Tausig was of opinion that they should be put up with the greatest economy, as public bodies were far too extravagant. Teleky agreed with the latter, as the sanatoria were only for the overflow of the existing institutions.

The result of the discussion on the methods of infection were that none can define one channel through which it passes at the exclusion of others—lungs, bowel, or skin are difficult to determine.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Suspected Case of Plague in Glasgow.—A suspected case of plague has occurred in the South Side of Glasgow, a district in which there is a considerable foreign population, and in which a limited outbreak of the disease occurred in 1900. The patient was at once removed to hospital, and as nearly a fortnight has elapsed since his isolation without the occurrence of any fresh cases, there seems no reason to fear that the experience of seven years ago will recur.

Rowdiness at the Glasgow University Graduation.—The ordinary degrees in Medicine and Law were conferred at the Graduation ceremonial held in the Bute Hall on November 7th. There was a crowded attendance, and rowdiness on the part of the students was a conspicuous feature of the proceedings, benches being torn up to make an arena for a private feud between the engineering and medical undergraduates, which was waged, however, without the knowledge of most of the audience, so great was the din of whistles and singing made by the other students present. The Principal made the usual appeal for silence prior to offering a Latin prayer, but the appeal, like the prayer itself, and the subsequent proceedings, was quite unheard. The whole of the ceremony, which lasted for half an hour, practically proceeded in dumb show, the graduates coming forward, being capped, and returning to their seats, the only evidence of their identity being that obtainable from the printed lists. Fortunately there were neither honorary graduates—who might have felt that they were being treated with discourtesy—nor orators, whose feelings required to be considered; in fact, a purely domestic row.

Edinburgh Royal Infirmary.—At their meeting on November 4th, the managers appointed Dr. Edwin Bramwell, F.R.C.P.Ed. and Lond., to be an Assistant Physician to the Royal Infirmary.

BELFAST.

Ulster Medical Society.—The opening meeting of the session was held in the Medical Institute on Thursday evening, November 7th, when the President, Dr. John McCaw, delivered an important and interesting address on "Tuberculosis in Childhood and its relation to Milk," which will be published at a later date. Dr. McCaw's long experience as physician at the Belfast Hospital for Sick Children, and his special attention to the diseases of childhood qualify him to deal with this subject, and though much has been said and written on tuberculosis of late, he succeeded in being fresh and interesting, as well as practical.

Public Health and the Registration of Deaths.—At the last meeting of the Public Health Committee a letter was read from the Chief Secretary for Ireland, in answer to a request that he should receive a deputation on the above subject. He points out that he is aware that no arrangements exist by which particulars of deaths occurring in the city are communicated to the sanitary authority, and that while he recognises the importance of such an arrangement, there is no way at present of bringing it into existence. He proposes, therefore, to consider whether it will not be possible to introduce legislation next session to apply Section 28 of the Registration of Births and Deaths Act, 1874, to Ireland. The section referred to requires every registrar to furnish a sanitary authority, when required by such authority, particulars of any deaths registered by him, on forms supplied by the sanitary authority, who shall pay twopence for such return, and a further sum of twopence for every death entered in the return.

LETTERS TO THE EDITOR.

THE CANCER PROBLEM.

To the Editor of The Medical Press and Circular.

Sir,—Among the various theories advanced as the cause of cancer, excess of nitrogenous diet seems to be a likely one, while others suppose that the meat from an unhealthy animal is a more probable cause. I have a strong suspicion myself that the large consumption of frozen meat, either supplied from abroad or killed here and kept in cold storage, should be just as likely a cause of cancer, if not more so. I have been informed by those who know that carcases of sheep are sometimes kept in a frozen condition for three years before being sent to the various retail shops. Could such meat be healthy to consume, even supposing (which requires a stretch of the imagination) that such carcases were those of healthy animals? The cold storage system I detest, as neither vendor nor purchaser can tell *when the animal was killed*. It would be interesting in this connection if reliable statistics could be obtained of the percentage of cancer cases in the United Kingdom before and subsequent to the introduction of this vile method of retarding decomposition by means of cold storage.

I am, Sir, yours truly,
Alexander Duke.

REVIEWS OF BOOKS.

BLOOD STAINS: THEIR DETECTION AND DETERMINATION (*a*).

The differentiation of blood stains from other stains, and the determination of the source of stains proved to be blood, is one that presents oftentimes very great difficulties—even to the skilled expert. To help the expert to come to a conclusion, a large number of tests—chemical, spectroscopic, serological, biological, and microscopical—have been devised. Some of these tests are satisfactory up to a certain point, and then fail; others are fallacious; while one or two have for years stood the closest investigation without our confidence in them being in any way lessened. In the case of all of them, however, certain details of technique must be followed, and some of our text-books on forensic medicine admittedly do not give sufficient details to allow the investigator to make the most of the tests at his disposal. For these reasons a book devoted entirely to the subject, in which no essential detail is omitted to make room for other matter, and in which practically the whole of the various tests are considered as to their faults and limitations, cannot but be of the highest service to the medico-legal expert. A bibliography containing some 336 references to the tests shows the enormous amount of work that Major Sutherland has devoted to the compilation of this volume, and his personal wide experience, his perspicacity, and his thorough and conscientious study have enabled him to produce a thoroughly trustworthy work, which we can with all confidence recommend to the coroner, the general practitioner, and to the worker in the clinical laboratory.

ANTISEPTIC METHODS (*b*).
